  "geometry_note": "Coarse conditional feasibility range, fixed TIC properties and simplified limb-darkened shape; not a
calibrated posterior. Check chi2 and grid boundaries in geometry.json."
}
```

No individual secondary exceeds3sigma. null-secondary.json tests covariance phases and widths: pointwise limits span0.58–4.81ppt and are not a uniform global upper bound. A faint companion and uncertain chord/radius/light ratio can account for a missing secondary; the assumed main-sequence radius is not a measured exclusion.

sector	secondary mid BTJD	error d	depth ppt	error ppt

[]
```

Current archives and novelty

SIMBAD exact Gaia-ID: [{"id": "Gaia DR3 2812131799856915968", "main_id": "UCAC4 517-141331", "otype": "SB*", "ra": "349.76188432019666", "dec": "13.285064206886112"}]. *This SB* classification establishes spectroscopy, not a prior eclipse discovery. Gaia vari_eclipsing_binary rows=0; vari_summary=[]; current ExoFOP={"toi_count": 0, "ctoi_count": 0}. Fresh shared VSX60arcsec result: {"B_vsx_vsx": []}. ROT is not prior eclipse classification. A cone neighbor must not be assigned to target.

Nine-catalog IDIA and Harvard cone requests each timed out (idia-receipts.json and idia-mirror-receipts.json). Consequently ASAS-SN, SB9, WDS, Kostov2/3/4, IJspeert and Prsa current per-object coverage is unavailable, not empty. Batched exact-name web queries on2026-10-30 returned no relevant source and do not prove novelty. Shared source receipts preserve current Gaia/VSX/SIMBAD/ExoFOP query provenance. The original paper/source records were checked live and remain unchanged.

Follow-up and predictions

Refine stellar radii, light ratio and RV/eclipsing joint orbit with resolved photometry or spectroscopy; retry unavailable catalogs before any novelty claim. Next fitted primary after2026-10-30: BTJD4344.01569, conditional linear-ephemeris1sigma=0.00095d. Next secondary template phase: BTJD4346.98314; phase/systematic uncertainty is uncalibrated, so do not use it as a precise scheduling window. For undetected secondary kinds use the Gaia covariance windows, not this optimized scan prediction.

Reviewed by fresh Sol lead G with fresh GPT-6.1 Terra numerical helper; measurements and script assumptions were independently inspected.

R056. TIC 150696021

physical_verdict: CONFIRMED

novelty_status: uncatalogued; original seven-group standard; prior ASAS-SN gap resolved 2026-10-30; reviews/2026-10-30-next70/shared-catalogues/previous-coverage-recovery

completion: COMPLETED_WITH_ARCHIVE_LIMITATION

next_check: Retry unavailable catalogs; refine joint orbit and stellar characterization.

Archived source: sanitized report text.

TIC 150696021: CONFIRMED

Seven primaries and five independently detected secondaries recur with the RV period. The G13.86 neighbor19.3 arcsec away is capable in a dilution-only test, but per-pixel regression in four events favors the target every time, with the free centroid on target. Physical EB is confirmed; geometry and component luminosities remain conditional.

Full review: COMPLETED_WITH_ARCHIVE_LIMITATION. Physical verdict is separate from novelty. Novelty: LIMITED_PRIOR_ART_COVERAGE; no prior target EB was established by the available current sources. New nine-catalog passes to both IDIA and Harvard timed out and are not negative matches.

Raw SAP and event measurements

Primary P=7.760015435 +/- 0.000012413 d; Tref=3154.8847230 +/- 0.0006042 BTJD at cycle42; T0=2828.9640747. 7 fitted primary events, O-C RMS=3.173 min; chi2/dof=17.66/5. Shape T14=5.765h, profile range=[0.2347758620689655, 0.24563793103448273], ingress fraction=0.35; T12=fr*T14 and nominal T23=T14-2*T12. Trapezoid flat time is not totality for grazing systems.

83	3581.6841192	0.000721	62.052	0.436	-2.092	0

Primary median depth=62.052ppt; maximum absolute background-regression fake depth=0.459ppt. Background native units were not treated as normalized flux. 0 event timing fits hit a scan edge. Quality-zero fits use exposure integration, local quadratic baselines, red-noise beta and grid floors; flagged-core counts and centroid/background regressions are retained in fit-results.json. Source variability and shape errors may exceed these conditional errors.

Blind rolling-median census covers all available sectors without the old post-gap trim. No off-eclipse census dip exceeds30%of the primary depth outside0.08phase of either fitted eclipse kind. Smaller candidates, gaps, sector edges and all threshold details remain in fit-results.json; this is a diagnostic census, not a calibrated false-positive probability.

Gaia and physical feasibility

Own-source SB1 covariance verified: bit_index=127,15 correlations in P,gamma,K1,e,omega,Tp order; omega-Tp correlation=0.9998698. Primary assigned conjunctionA; period discrepancy=1.585sigma. ConjunctionA at Gaia epoch: offset=-0.027202d, Gaia-only sigma=0.045108d; including photometric extrapolation sigma=0.045329d. Full epoch-by-epoch comparisons are retained in orbit-gates.json. ConjunctionB at Gaia epoch: offset=-3.836545d, Gaia-only sigma=0.032742d; including photometric extrapolation sigma=0.033046d. Full epoch-by-epoch comparisons are retained in orbit-gates.json.

Limb-darkened two-sphere feasibility permits free primary/secondary flux scales and fixed TIC stellar dimensions. It does not identify the foreground component from eclipse depth alone. Using Gaia primary spectroscopic omega and positive RV away from the observer, at A (nu+omega=90deg) the RV primary is behind and the companion is foreground; at B (270deg) the primary is foreground. The deeper eclipse is assigned A here; luminosity and component labeling remain conditional. Minimum RV companion mass and eclipse luminosity/shape jointly allow a stellar companion.

  "caution": "Same TESS pixels as QLP, independent aperture reduction. Approximate circular Gaussian PSF calibrated to multi-star out-of-eclipse image; formal chi2 excludes PSF mismatch, correlated pixels/time and sector-level systematics. No formal significance from delta-chi2; compare event repeatability and residuals. Aperture depth errors are white-noise conditional only; degree comparison probes baseline sensitivity."
}
```

Individual event source comparisons are in pixel-localization.json; approximate PSF chi-square excludes model/correlated-noise errors and is not formal localization significance.

Current archives and novelty

SIMBAD exact Gaia-ID: [{"id": "Gaia DR3 1881109883677907584", "main_id": "TYC 2227-1936-1", "otype": "SB*", "ra": "338.41975979931", "dec": "26.97456707901"}]. *This SB* classification establishes spectroscopy, not a prior eclipse discovery. Gaia vari_eclipsing_binary rows=0; vari_summary=[]; current ExoFOP={"toi_count": 0, "ctoi_count": 0}. Fresh shared VSX60arcsec result: {"B_vsx_vsx": [{"_r": "19.62", "Name": "Gaia DR3 1881109883677908224", "Type": "ROT", "Period": "", "RAJ2000": "338.42587", "DEJ2000": "26.97467"}]}. ROT is not prior eclipse classification. A cone neighbor must not be assigned to target.

Nine-catalog IDIA and Harvard cone requests each timed out (idia-receipts.json and idia-mirror-receipts.json). Consequently ASAS-SN, SB9, WDS, Kostov2/3/4, IJspeert and Prsa current per-object coverage is unavailable, not empty. Batched exact-name web queries on2026-10-30 returned no relevant source and do not prove novelty. Shared source receipts preserve current Gaia/VSX/SIMBAD/ExoFOP query provenance. The original paper/source records were checked live and remain unchanged.

Follow-up and predictions

Refine stellar radii, light ratio and RV/eclipsing joint orbit with resolved photometry or spectroscopy; retry unavailable catalogs before any novelty claim. Next fitted primary after2026-10-30: BTJD4349.92710, conditional linear-ephemeris1sigma=0.00200d. Next secondary template phase: BTJD4346.04969; phase/systematic uncertainty is uncalibrated, so do not use it as a precise scheduling window. For undetected secondary kinds use the Gaia covariance windows, not this optimized scan prediction.

Reviewed by fresh Sol lead G with fresh GPT-6.1 Terra numerical helper; measurements and script assumptions were independently inspected.

R057. TIC 345050437

physical_verdict: CONFIRMED

novelty_status: uncatalogued; original seven-group standard; prior ASAS-SN gap resolved 2026-10-30; reviews/2026-10-30-next70/shared-catalogues/previous-coverage-recovery

completion: COMPLETED_WITH_ARCHIVE_LIMITATION

next_check: Retry unavailable catalogs; refine joint orbit and stellar characterization.

Archived source: sanitized report text.

TIC 345050437: CONFIRMED

Thirty-three primaries and repeated secondaries establish a coherent EB. The old high PSF residual is not accepted uncritically: fresh template regression favors the target in every usable sector24 event and its free centroid is only2.97 arcsec away. A known E-type variable44.25 arcsec away has period2.5355d, inconsistent with the target4.48083d clock. Elevated geometry chi-square precludes precise radii/orbit claims.

Full review: COMPLETED_WITH_ARCHIVE_LIMITATION. Physical verdict is separate from novelty. Novelty: LIMITED_PRIOR_ART_COVERAGE; no prior target EB was established by the available current sources. New nine-catalog passes to both IDIA and Harvard timed out and are not negative matches.

Raw SAP and event measurements

Primary P=4.480834621 +/- 0.000001500 d; Tref=2910.6551981 +/- 0.0001744 BTJD at cycle255; T0=1768.0423698. 33 fitted primary events, O-C RMS=1.518 min; chi2/dof=47.90/31. Primary median depth=64.791ppt; maximum absolute background-regression fake depth=1.579ppt. Background native units were not treated as normalized flux. 0 event timing fits hit a scan edge. Quality-zero fits use exposure integration, local quadratic baselines, red-noise beta and grid floors; flagged-core counts and centroid/background regressions are retained in fit-results.json. Source variability and shape errors may exceed these conditional errors.

Blind rolling-median census covers all available sectors without the old post-gap trim. No off-eclipse census dip exceeds30%of the primary depth outside0.08phase of either fitted eclipse kind. Smaller candidates, gaps, sector edges and all threshold details remain in fit-results.json; this is a diagnostic census, not a calibrated false-positive probability.

Gaia and physical feasibility

Own-source SB1 covariance verified: bit_index=127,15 correlations in P,gamma,K1,e,omega,Tp order; omega-Tp correlation=0.9999283. Primary assigned conjunctionA; period discrepancy=-1.904sigma. ConjunctionA at Gaia epoch: offset=-0.003781d, Gaia-only sigma=0.022320d; including photometric extrapolation sigma=0.022336d. Full epoch-by-epoch comparisons are retained in orbit-gates.json. ConjunctionB at Gaia epoch: offset=2.220511d, Gaia-only sigma=0.020657d; including photometric extrapolation sigma=0.020675d. Full epoch-by-epoch comparisons are retained in orbit-gates.json.

Limb-darkened two-sphere feasibility permits free primary/secondary flux scales and fixed TIC stellar dimensions. It does not identify the foreground component from eclipse depth alone. Using Gaia primary spectroscopic omega and positive RV away from the observer, at A (nu+omega=90deg) the RV primary is behind and the companion is foreground; at B (270deg) the primary is foreground. The deeper eclipse is assigned A here; luminosity and component labeling remain conditional. Minimum RV companion mass and eclipse luminosity/shape jointly allow a stellar companion.

}
```

Individual event source comparisons are in pixel-localization.json; approximate PSF chi-square excludes model/correlated-noise errors and is not formal localization significance.

Current archives and novelty

SIMBAD exact Gaia-ID: [{"id": "Gaia DR3 2011135311287080704", "main_id": "TYC 4012-825-1", "otype": "SB*", "ra": "355.34922032052", "dec": "59.51927035952001"}]. This SB* classification establishes spectroscopy, not a prior eclipse discovery. Gaia vari_eclipsing_binary rows=0; vari_summary=[]; current ExoFOP={"toi_count": 0, "ctoi_count": 0}. Fresh shared VSX60arcsec result: {"B_vsx_vsx": [{"_r": "44.25", "Name": "Gaia DR3 2011136788755832704", "Type": "E", "Period": "2.535500000000", "RAJ2000": "355.37332", "DEJ2000": "59.52063"}]}. ROT is not prior eclipse classification. A cone neighbor must not be assigned to target.

Nine-catalog IDIA and Harvard cone requests each timed out (idia-receipts.json and idia-mirror-receipts.json). Consequently ASAS-SN, SB9, WDS, Kostov2/3/4, IJspeert and Prsa current per-object coverage is unavailable, not empty. Batched exact-name web queries on2026-10-30 returned no relevant source and do not prove novelty. Shared source receipts preserve current Gaia/VSX/SIMBAD/ExoFOP query provenance. The original paper/source records were checked live and remain unchanged.

Follow-up and predictions

Refine stellar radii, light ratio and RV/eclipsing joint orbit with resolved photometry or spectroscopy; retry unavailable catalogs before any novelty claim. Next fitted primary after2026-10-30: BTJD4344.52228, conditional linear-ephemeris1sigma=0.00051d. Next secondary template phase: BTJD4346.76602; phase/systematic uncertainty is uncalibrated, so do not use it as a precise scheduling window. For undetected secondary kinds use the Gaia covariance windows, not this optimized scan prediction.

Reviewed by fresh Sol lead G with fresh GPT-6.1 Terra numerical helper; measurements and script assumptions were independently inspected.

R058. TIC 236531158

physical_verdict: PROBABLE

novelty_status: uncatalogued; seven-group coverage recovered; dated tier reconciliation 2026-10-30

completion: COMPLETED_WITH_ARCHIVE_LIMITATION

next_check: Repeated eclipses secure; host attribution/check unresolved. See dated tier reconciliation and unchanged historical report.

Archived source: sanitized report text.

TIC 236531158: PLAUSIBLE

The eclipsing signal is secure, with27 primaries and28 individually detected secondary events, but the host remains materially ambiguous. Free-amplitude calibrated circular/elliptical models favor the12arcsec G13.84 neighbor in13/13 events; enforcing Gaia-G flux ratios flips the result to target in13/13 events. PSF/color/dilution calibration is not controlled sufficiently to resolve this model dependence. PLAUSIBLE refers to the assigned target EB; it is not a claim that the eclipse signal itself is doubtful.

Full review: COMPLETED_WITH_ARCHIVE_LIMITATION. Physical verdict is separate from novelty. Novelty: LIMITED_PRIOR_ART_COVERAGE; no prior target EB was established by the available current sources. New nine-catalog passes to both IDIA and Harvard timed out and are not negative matches.

Primary median depth=64.862ppt; maximum absolute background-regression fake depth=0.728ppt. Background native units were not treated as normalized flux. 0 event timing fits hit a scan edge. Quality-zero fits use exposure integration, local quadratic baselines, red-noise beta and grid floors; flagged-core counts and centroid/background regressions are retained in fit-results.json. Source variability and shape errors may exceed these conditional errors.

Blind rolling-median census covers all available sectors without the old post-gap trim. No off-eclipse census dip exceeds30%of the primary depth outside0.08phase of either fitted eclipse kind. Smaller candidates, gaps, sector edges and all threshold details remain in fit-results.json; this is a diagnostic census, not a calibrated false-positive probability.

Gaia and physical feasibility

Own-source SB1 covariance verified: bit_index=127,15 correlations in P,gamma,K1,e,omega,Tp order; omega-Tp correlation=0.99966836. Primary assigned conjunctionA; period discrepancy=-0.532sigma. ConjunctionA at Gaia epoch: offset=0.012333d, Gaia-only sigma=0.015010d; including photometric extrapolation sigma=0.015025d. Full epoch-by-epoch comparisons are retained in orbit-gates.json. ConjunctionB at Gaia epoch: offset=0.996579d, Gaia-only sigma=0.008721d; including photometric extrapolation sigma=0.008747d. Full epoch-by-epoch comparisons are retained in orbit-gates.json.

Mass-function/assumed-stellar-radius checks (not measured binary parameters):

Limb-darkened two-sphere feasibility permits free primary/secondary flux scales and fixed TIC stellar dimensions. It does not identify the foreground component from eclipse depth alone. Using Gaia primary spectroscopic omega and positive RV away from the observer, at A (nu+omega=90deg) the RV

primary is behind and the companion is foreground; at B (270deg) the primary is foreground. The deeper eclipse is assigned A here; luminosity and component labeling remain conditional. Minimum RV companion mass and eclipse luminosity/shape jointly allow a stellar companion.

Current archives and novelty

SIMBAD exact Gaia-ID: [{"id": "Gaia DR3 1866269775241800320", "main_id": "TYC 2692-150-1", "otype": "SB*", "ra": "314.55257938221996", "dec": "33.4973524698"}]. *This SB* classification establishes spectroscopy, not a prior eclipse discovery. Gaia vari_eclipsing_binary rows=0; vari_summary=[]; current ExoFOP={"toi_count": 0, "ctoi_count": 0}. Fresh shared VSX60arcsec result: {"B_vsx_vsx": []}. ROT is not prior eclipse classification. A cone neighbor must not be assigned to target.

Nine-catalog IDIA and Harvard cone requests each timed out (idia-receipts.json and idia-mirror-receipts.json). Consequently ASAS-SN, SB9, WDS, Kostov2/3/4, IJspeert and Prsa current per-object coverage is unavailable, not empty. Batched exact-name web queries on2026-10-30 returned no relevant source and do not prove novelty. Shared source receipts preserve current Gaia/VSX/SIMBAD/ExoFOP query provenance. The original paper/source records were checked live and remain unchanged.

Follow-up and predictions

Obtain a calibrated empirical TESS PRF with color-dependent neighbor fluxes or ground-based resolved eclipse photometry of the target and12arcsec neighbor. Next fitted primary after2026-10-30: BTJD4344.53469, conditional linear-ephemeris1sigma=0.00043d. Next secondary template phase: BTJD4343.52484; phase/systematic uncertainty is uncalibrated, so do not use it as a precise scheduling window. For undetected secondary kinds use the Gaia covariance windows, not this optimized scan prediction.

Reviewed by fresh Sol lead G with fresh GPT-6.1 Terra numerical helper; measurements and script assumptions were independently inspected.

R059. TIC 415751695

physical_verdict: CONFIRMED

novelty_status: uncatalogued; original seven-group standard; prior ASAS-SN gap resolved 2026-10-30; reviews/2026-10-30-next70/shared-catalogues/previous-coverage-recovery

completion: COMPLETED_WITH_ARCHIVE_LIMITATION

next_check: Retry unavailable catalogs; refine joint orbit and stellar characterization.

Archived source: sanitized report text.

TIC 415751695: CONFIRMED

Twenty-one primaries and twenty secondary events plus independent TARS recovery establish a repeated EB. The old PSF residual0.931 is addressed by fresh regression: free deficit centroid2.97arcsec from target with fractional residual0.177 and no G<15 capable neighbor. No precise parameter inference follows from this approximate PSF model.

Full review: COMPLETED_WITH_ARCHIVE_LIMITATION. Physical verdict is separate from novelty. Novelty: LIMITED_PRIOR_ART_COVERAGE; no prior target EB was established by the available current sources. New nine-catalog passes to both IDIA and Harvard timed out and are not negative matches.

100	4097.7291494	0.000502	55.940	0.296	-1.359	0

Primary median depth=61.640ppt; maximum absolute background-regression fake depth=0.744ppt. Background native units were not treated as normalized flux. 0 event timing fits hit a scan edge. Quality-zero fits use exposure integration, local quadratic baselines, red-noise beta and grid floors; flagged-core counts and centroid/background regressions are retained in fit-results.json. Source variability and shape errors may exceed these conditional errors.

Blind rolling-median census covers all available sectors without the old post-gap trim. No off-eclipse census dip exceeds30%of the primary depth outside0.08phase of either fitted eclipse kind. Smaller candidates, gaps, sector edges and all threshold details remain in fit-results.json; this is a diagnostic census, not a calibrated false-positive probability.

Gaia and physical feasibility

Own-source SB1 covariance verified: bit_index=127,15 correlations in P,gamma,K1,e,omega,Tp order; omega-Tp correlation=0.9995584. Primary assigned conjunctionA; period discrepancy=0.544sigma. ConjunctionA at Gaia epoch: offset=-0.050309d, Gaia-only sigma=0.050469d; including photometric extrapolation sigma=0.050471d. Full epoch-by-epoch comparisons are retained in orbit-gates.json. ConjunctionB at Gaia epoch: offset=-2.485075d, Gaia-only sigma=0.043945d; including photometric extrapolation sigma=0.043948d. Full epoch-by-epoch comparisons are retained in orbit-gates.json.

Limb-darkened two-sphere feasibility permits free primary/secondary flux scales and fixed TIC stellar dimensions. It does not identify the foreground component from eclipse depth alone. Using Gaia primary spectroscopic omega and positive RV away from the observer, at A (nu+omega=90deg) the RV primary is behind and the companion is foreground; at B (270deg) the primary is foreground. The deeper eclipse is assigned A here; luminosity and component labeling remain conditional. Minimum RV companion mass and eclipse luminosity/shape jointly allow a stellar companion.

```

Individual event source comparisons are in pixel-localization.json; approximate PSF chi-square excludes model/correlated-noise errors and is not formal localization significance.

Current archives and novelty

SIMBAD exact Gaia-ID: [{"id": "Gaia DR3 3549629597848975872", "main_id": "TYC 6082-305-1", "otype": "SB*", "ra": "164.63570637693", "dec": "-22.10958257191"}]. *This SB* classification establishes spectroscopy, not a prior eclipse discovery. Gaia vari_eclipsing_binary rows=0; vari_summary=[]; current ExoFOP={"toi_count": 0, "ctoi_count": 0}. Fresh shared VSX60arcsec result: {"B_vsx_vsx": []}. ROT is not prior eclipse classification. A cone neighbor must not be assigned to target.

Nine-catalog IDIA and Harvard cone requests each timed out (idia-receipts.json and idia-mirror-receipts.json). Consequently ASAS-SN, SB9, WDS, Kostov2/3/4, IJspeert and Prsa current per-object coverage is unavailable, not empty. Batched exact-name web queries on2026-10-30 returned no relevant source and do not prove novelty. Shared source receipts preserve current Gaia/VSX/SIMBAD/ExoFOP query provenance. The original paper/source records were checked live and remain unchanged.

Follow-up and predictions

Refine stellar radii, light ratio and RV/eclipsing joint orbit with resolved photometry or spectroscopy; retry unavailable catalogs before any novelty claim. Next fitted primary after2026-10-30: BTJD4347.52992, conditional linear-ephemeris1sigma=0.00026d. Next secondary template phase: BTJD4345.03374; phase/systematic uncertainty is uncalibrated, so do not use it as a precise scheduling window. For undetected secondary kinds use the Gaia covariance windows, not this optimized scan prediction.

Reviewed by fresh Sol lead G with fresh GPT-6.1 Terra numerical helper; measurements and script assumptions were independently inspected.

R060. TIC 335862015

physical_verdict: CONFIRMED

novelty_status: uncatalogued; original seven-group standard; prior ASAS-SN gap resolved 2026-10-30; reviews/2026-10-30-next70/shared-catalogues/previous-coverage-recovery

completion: COMPLETED_WITH_ARCHIVE_LIMITATION

next_check: Retry unavailable catalogs; refine joint orbit and stellar characterization.

Archived source: sanitized report text.

TIC 335862015: CONFIRMED

Three deep primary and two secondary events in sector91, recovered by TARS and localized to target against a capable49.5arcsec neighbor in all three events, establish a physical EB. The short baseline, poor fixed-TIC geometry and discrepant Gaia-median secondary phase require future orbit/stellar characterization; they do not erase the localized eclipses.

Full review: COMPLETED_WITH_ARCHIVE_LIMITATION. Physical verdict is separate from novelty. Novelty: LIMITED_PRIOR_ART_COVERAGE; no prior target EB was established by the available current sources. New nine-catalog passes to both IDIA and Harvard timed out and are not negative matches.

Raw SAP and event measurements

Primary P=6.577232276 +/- 0.000439950 d; Tref=3790.2187995 +/- 0.0005680 BTJD at cycle2; T0=3777.0643350. 3 fitted primary events, O-C RMS=0.422 min; chi2/dof=0.29/1. Shape T14=7.603h, profile range=[0.30892499999999995, 0.324675], ingress fraction=0.25; T12=fr*T14 and nominal T23=T14-2*T12. Trapezoid flat time is not totality for grazing systems.

sector	mid BTJD	error d	depth ppt	error ppt	O-C min	flagged core
91	3777.0641992	0.000950	64.194	0.609	-0.196	0
91	3790.2192068	0.000950	64.158	0.556	0.587	0
91	3796.7957603	0.000950	64.514	0.565	-0.391	0

Primary median depth=64.194ppt; maximum absolute background-regression fake depth=0.017ppt. Background native units were not treated as normalized flux. 0 event timing fits hit a scan edge. Quality-zero fits use exposure integration, local quadratic baselines, red-noise beta and grid floors; flagged-core counts and centroid/background regressions are retained in fit-results.json. Source variability and shape errors may exceed these conditional errors.

Blind rolling-median census covers all available sectors without the old post-gap trim. No off-eclipse census dip exceeds30%of the primary depth outside0.08phase of either fitted eclipse kind. Smaller candidates, gaps, sector edges and all threshold details remain in fit-results.json; this is a diagnostic census, not a calibrated false-positive probability.

Gaia and physical feasibility

Own-source SB1 covariance verified: bit_index=127,15 correlations in P,gamma,K1,e,omega,Tp order; omega-Tp correlation=0.9971951. Primary assigned conjunctionA; period discrepancy=-0.676sigma. ConjunctionA at Gaia epoch: offset=0.403832d, Gaia-only sigma=0.067549d; including photometric extrapolation sigma=0.237324d. Full epoch-by-epoch comparisons are retained in orbit-gates.json. ConjunctionB at Gaia epoch: offset=-3.120511d, Gaia-only sigma=0.101962d; including photometric extrapolation sigma=0.249311d. Full epoch-by-epoch comparisons are retained in orbit-gates.json.

Limb-darkened two-sphere feasibility permits free primary/secondary flux scales and fixed TIC stellar dimensions. It does not identify the foreground component from eclipse depth alone. Using Gaia primary spectroscopic omega and positive RV away from the observer, at A (nu+omega=90deg) the RV primary is behind and the companion is foreground; at B (270deg) the primary is foreground. The deeper eclipse is assigned A here; luminosity and component labeling remain conditional. Minimum RV companion mass and eclipse luminosity/shape jointly allow a stellar companion.

Individual event source comparisons are in pixel-localization.json; approximate PSF chi-square excludes model/correlated-noise errors and is not formal localization significance.

Current archives and novelty

SIMBAD exact Gaia-ID: [{"id": "Gaia DR3 6310152211684175104", "main_id": "TYC 6168-1001-1", "otype": "SB*", "ra": "224.21401891473", "dec": "-15.157451048150003"}]. *This SB* classification establishes spectroscopy, not a prior eclipse discovery. Gaia vari_eclipsing_binary rows=0; vari_summary=[]; current ExoFOP={"toi_count": 0, "ctoi_count": 0}. Fresh shared VSX60arcsec result: {"B_vsx_vsx": []}. ROT is not prior eclipse classification. A cone neighbor must not be assigned to target.

Nine-catalog IDIA and Harvard cone requests each timed out (idia-receipts.json and idia-mirror-receipts.json). Consequently ASAS-SN, SB9, WDS, Kostov2/3/4, IJspeert and Prsa current per-object coverage is unavailable, not empty. Batched exact-name web queries on2026-10-30 returned no relevant source and do not prove novelty. Shared source receipts preserve current Gaia/VSX/SIMBAD/ExoFOP query provenance. The original paper/source records were checked live and remain unchanged.

Follow-up and predictions

Refine stellar radii, light ratio and RV/eclipsing joint orbit with resolved photometry or spectroscopy; retry unavailable catalogs before any novelty claim. Next fitted primary after2026-10-30: BTJD4349.28354, conditional linear-ephemeris1sigma=0.03740d. Next secondary template phase:

BTJD4345.99675; phase/systematic uncertainty is uncalibrated, so do not use it as a precise scheduling window. For undetected secondary kinds use the Gaia covariance windows, not this optimized scan prediction.

Reviewed by fresh Sol lead G with fresh GPT-6.1 Terra numerical helper; measurements and script assumptions were independently inspected.

R061. TIC 211231319

physical_verdict: CONFIRMED

novelty_status: uncatalogued; original seven-group standard; prior ASAS-SN gap resolved 2026-10-30; reviews/2026-10-30-next70/shared-catalogues/previous-coverage-recovery

completion: COMPLETE (adjudicated)

next_check: Joint diluted light-curve/RV modelling to refine radii, flux ratio and small-e geometry.

Archived source: sanitized report text.

TIC 211231319: CONFIRMED

Repeated primary and secondary eclipses, independent SPOC recovery, own Gaia timing and on-target deficit establish a target EB; no bright capable neighbor.

Full review: COMPLETE (adjudicated). Novelty: LIMITED; successful checks found no target EB classification, but several catalogues were unavailable.

Raw untrimmed QUALITY=0 SAP: 11 accepted primary fits; median depth62.881ppt; T14=5.0599h. Primary and secondary individual timing/depth errors, duration/ingress/flat coordinates, O-C and rejected windows are tabulated below. Errors are conditional on shape/local baseline with grid and red-noise inflation. Trapezoid flat time is not measured totality.

Ancillary log block 1: 634 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Raw-event controls and coverage

Background regressions use standardized native background units, not normalized flux ratios. Event records retain flagged-core counts, background-regressed depth and centroid template shifts. Centroid shifts are diagnostics, not source attribution. The blind rolling-median census below is diagnostic and uncalibrated; off-phase triggers, known common-mode sector times and shallow systematics must not be promoted to extra eclipses. Missing/flagged windows are not nulls.

Ancillary log block 2: 240 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Own Gaia covariance and physical feasibility

Source identity, solution layout and bit order were asserted before covariance sampling. No borrowed correlations. Per-event conjunction predictions and residuals, period tension, mass function, companion minimum mass, orbital scale and central duration estimates follow. TIC properties and assumed companion radii are feasibility inputs, not measured dimensions. Two-disk limb-darkened models account for partial overlap; poor fits/grid edges prevent calibrated e sin omega or component posterior claims.

Ancillary log block 3: 764 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Independent reduction and source attribution

Exact target and sector FITS identities were validated. This is a different pipeline using the same TESS pixels, not another observatory. Linear/quadratic baseline and background-sensitive depths are retained; aperture/PDCSAP depth differences reflect dilution and processing. TARS has no quality column.

Ancillary log block 4: 206 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

R064. TIC 1989681813

physical_verdict: PLAUSIBLE

novelty_status: unresolved; original catalogue standard incomplete or physical verdict plausible; reviews/novelty-reconciliation/README.md

completion: COMPLETE (adjudicated)

next_check: Obtain spatially resolved time-series photometry across a later narrow deficit and both Gaia conjunctions; use empirical calibrated TESS PRFs in a second sector to distinguish astrophysical deficit from nonstationary spatial contamination.

Archived source: sanitized report text.

TIC 1989681813: PLAUSIBLE

Later sectors retain a narrow recurring deficit after smooth tidal/harmonic removal, but broad/nonstationary earlier waveforms and complex deficit image (target residual0.991, free location22arcsec away) prevent secure eclipse/source interpretation. PLAUSIBLE after targeted broad-shape and tide tests.

Full review: COMPLETE (adjudicated). Novelty: LIMITED; successful checks found no target EB classification, but several catalogues were unavailable.

Raw untrimmed QUALITY=0 SAP: 9 accepted primary fits; median depth71.178ppt; T14=14.4072h. Primary and secondary individual timing/depth errors, duration/ingress/flat coordinates, O-C and rejected windows are tabulated below. Errors are conditional on shape/local baseline with grid and red-noise inflation. Trapezoid flat time is not measured totality.

Ancillary log block 1: 483 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Raw-event controls and coverage

Background regressions use standardized native background units, not normalized flux ratios. Event records retain flagged-core counts, background-regressed depth and centroid template shifts. Centroid shifts are diagnostics, not source attribution. The blind rolling-median census below is diagnostic and uncalibrated; off-phase triggers, known common-mode sector times and shallow systematics must not be promoted to extra eclipses. Missing/flagged windows are not nulls.

Ancillary log block 2: 285 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Own Gaia covariance and physical feasibility

Source identity, solution layout and bit order were asserted before covariance sampling. No borrowed correlations. Per-event conjunction predictions and residuals, period tension, mass function, companion minimum mass, orbital scale and central duration estimates follow. TIC properties and

assumed companion radii are feasibility inputs, not measured dimensions. Two-disk limb-darkened models account for partial overlap; poor fits/grid edges prevent calibrated e sin omega or component posterior claims.

Ancillary log block 3: 640 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Other-conjunction windows and width/phase-grid limits follow. These are pointwise conditional template limits, not a uniform simultaneous confidence bound; coverage varies.

Ancillary log block 4: 10348 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Broad waveform follow-up: sector-specific tide+harmonic baseline versus added broad/narrow trapezoid. RSS gains are descriptive; no calibrated model-selection probability. This supersedes interpreting the common grid-edge shape as a physical duration.

One bounded Harvard multi-catalogue mirror probe timed out after batchG reported all IDIA9 requests timing out. ASAS-SN, SB9, WDS, Prsa, IJspeert and Kostov tables therefore remain unchecked in this fresh pass; failed service is not a negative match. VSX raw table sections were inspected; no target EB rows found. General web searches on the ten exact SIMBAD names plus eclipsing/binary found only unrelated results, not exact-target prior publications. This does not establish novelty or a complete bibliography.

Predictions and deciding next check

AtBTJD4344.32880: next primary~4350.48570; other conjunction~4355.24293. Photometric extrapolations are scheduling estimates, conditional on stationary orbit; for1989681813 neither is a reliable physical eclipse ephemeris. For null secondary use Gaia phase uncertainty, not the single date.

Obtain spatially resolved time-series photometry across a later narrow deficit and both Gaia conjunctions; use empirical calibrated TESS PRFs in a second sector to distinguish astrophysical deficit from nonstationary spatial contamination.

Final adjudication: **PLAUSIBLE**. Later sectors retain a narrow recurring deficit after smooth tidal/harmonic removal, but broad/nonstationary earlier waveforms and complex deficit image (target residual0.991, free location22arcsec away) prevent secure eclipse/source interpretation. PLAUSIBLE after targeted broad-shape and tide tests.

Reproducibility: scripts and manifests retained in this batch. Original source audit completed before work; no source/paper edits or commits.

Lead control audit: {"median_primary_ppt": 71.17807741090103, "offphase_census_triggers": 21, "max_offphase_census_ppt": 665.7661206505501, "minimum_bg_regressed_depth_ratio": 0.8106702617464214}. Census trigger centers/durations can merge broad eclipse wings, especially253923749; they are not a calibrated blind-search catalog.1989681813 has large off-phase structure and remains plausible.

R065. TIC 250742811

physical_verdict: PROBABLE

novelty_status: uncatalogued; seven-group coverage recovered; dated tier reconciliation 2026-10-30

completion: COMPLETE (adjudicated)

next_check: Repeated eclipses secure; host attribution/check unresolved. See dated tier reconciliation and unchanged historical report.

Archived source: sanitized report text.

TIC 250742811: PLAUSIBLE

The two-kind EB signal is secure, but target versus nearly equally bright3.70arcsec companion remains ambiguous. Circular PSF favors target; expanded calibration reverses preference and event rankings. RV agreement supports target but cannot resolve the contradictory localization.

Full review: COMPLETE (adjudicated). Novelty: LIMITED; successful checks found no target EB classification, but several catalogues were unavailable.

Raw untrimmed QUALITY=0 SAP: 7 accepted primary fits; median depth64.993ppt; T14=6.5470h. Primary and secondary individual timing/depth errors, duration/ingress/flat coordinates, O-C and rejected windows are tabulated below. Errors are conditional on shape/local baseline with grid and red-noise inflation. Trapezoid flat time is not measured totality.

Ancillary log block 1: 481 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Raw-event controls and coverage

Background regressions use standardized native background units, not normalized flux ratios. Event records retain flagged-core counts, background-regressed depth and centroid template shifts. Centroid shifts are diagnostics, not source attribution. The blind rolling-median census below is diagnostic and uncalibrated; off-phase triggers, known common-mode sector times and shallow systematics must not be promoted to extra eclipses. Missing/flagged windows are not nulls.

Ancillary log block 2: 177 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Own Gaia covariance and physical feasibility

Source identity, solution layout and bit order were asserted before covariance sampling. No borrowed correlations. Per-event conjunction predictions and residuals, period tension, mass function, companion minimum mass, orbital scale and central duration estimates follow. TIC properties and assumed companion radii are feasibility inputs, not measured dimensions. Two-disk limb-darkened models account for partial overlap; poor fits/grid edges prevent calibrated e sin omega or component posterior claims.

Ancillary log block 3: 631 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Independent reduction and source attribution

Exact target and sector FITS identities were validated. This is a different pipeline using the same TESS pixels, not another observatory. Linear/quadratic baseline and background-sensitive depths are retained; aperture/PDCSAP depth differences reflect dilution and processing. TARS has no quality column.

Ancillary log block 4: 146 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

AtBTJD4344.32880: next primary~4351.63910; other conjunction~4357.64009. Photometric extrapolations are scheduling estimates, conditional on stationary orbit. For null secondary use Gaia phase uncertainty, not the single date.

Joint diluted light-curve/RV modelling to refine radii, flux ratio and small-e geometry.

Final adjudication: **CONFIRMED**. Eight primary and nine secondary events, independent SPOC and target-localized deficit establish an EB. The real secondary atphase0.3408 is recovered repeatedly despite the Gaia-median fixed-phase test missing it.

Reproducibility: scripts and manifests retained in this batch. Original source audit completed before work; no source/paper edits or commits.

Lead control audit: {"median_primary_ppt": 65.72142094457375, "offphase_census_triggers": 1, "max_offphase_census_ppt": 3.3503941987336194, "minimum_bg_regressed_depth_ratio": 0.9965604850086657}. Census trigger centers/durations can merge broad eclipse wings, especially253923749; they are not a calibrated blind-search catalog. VSX neighbor Gaia DR3 5564099590459295616 at48.12arcsec is DSCT|GDOR|SXPHE; it is not target prior EB classification.

R067. TIC 351541670

physical_verdict: PROBABLE

novelty_status: uncatalogued; seven-group coverage recovered; dated tier reconciliation 2026-10-30

completion: COMPLETE (adjudicated)

next_check: Repeated eclipses secure; host attribution/check unresolved. See dated tier reconciliation and unchanged historical report.

Archived source: sanitized report text.

TIC 351541670: PLAUSIBLE

The two-kind EB is secure but host unresolved: circular calibration favors target while expanded calibration moves to21.77arcsec neighbor and a large WCS shift. A capable1.23arcsec companion also remains unresolved. Ranking depends on calibration; no unique host is claimed.

Full review: COMPLETE (adjudicated). Novelty: LIMITED; successful checks found no target EB classification, but several catalogues were unavailable.

Raw untrimmed QUALITY=0 SAP: 8 accepted primary fits; median depth65.265ppt; T14=4.1909h. Primary and secondary individual timing/depth errors, duration/ingress/flat coordinates, O-C and rejected windows are tabulated below. Errors are conditional on shape/local baseline with grid and red-noise inflation. Trapezoid flat time is not measured totality.

Ancillary log block 1: 635 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Raw-event controls and coverage

Background regressions use standardized native background units, not normalized flux ratios. Event records retain flagged-core counts, background-regressed depth and centroid template shifts. Centroid shifts are diagnostics, not source attribution. The blind rolling-median census below is diagnostic and uncalibrated; off-phase triggers, known common-mode sector times and shallow systematics must not be promoted to extra eclipses. Missing/flagged windows are not nulls.

Ancillary log block 2: 213 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Own Gaia covariance and physical feasibility

Source identity, solution layout and bit order were asserted before covariance sampling. No borrowed correlations. Per-event conjunction predictions and residuals, period tension, mass function, companion minimum mass, orbital scale and central duration estimates follow. TIC properties and assumed companion radii are feasibility inputs, not measured dimensions. Two-disk limb-darkened models account for partial overlap; poor fits/grid edges prevent calibrated e sin omega or component posterior claims.

Ancillary log block 3: 703 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Independent reduction and source attribution

Exact target and sector FITS identities were validated. This is a different pipeline using the same TESS pixels, not another observatory. Linear/quadratic baseline and background-sensitive depths are retained; aperture/PDCSAP depth differences reflect dilution and processing. TARS has no quality column.

Ancillary log block 4: 271 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

One bounded Harvard multi-catalogue mirror probe timed out after batchG reported all IDIA9 requests timing out. ASAS-SN, SB9, WDS, Prsa, IJspeert and Kostov tables therefore remain unchecked in this fresh pass; failed service is not a negative match. VSX raw table sections were inspected; no target EB rows found. General web searches on the ten exact SIMBAD names plus eclipsing/binary found only unrelated results, not exact-target prior publications. This does not establish novelty or a complete bibliography.

Predictions and deciding next check

AtBTJD4344.32880: next primary~4347.28711; other conjunction~4345.20557. Photometric extrapolations are scheduling estimates, conditional on stationary orbit. For null secondary use Gaia phase uncertainty, not the single date.

Spatially resolved eclipse photometry must distinguish the21.77arcsec neighbor and the target/1.23arcsec pair; empirical PRF/WCS calibration in a second sector is the immediate archival deciding test.

Final adjudication: **PLAUSIBLE**. The two-kind EB is secure but host unresolved: circular calibration favors target while expanded calibration moves to21.77arcsec neighbor and a large WCS shift. A capable1.23arcsec companion also remains unresolved. Ranking depends on calibration; no unique host is claimed.

Own Gaia covariance and physical feasibility

Source identity, solution layout and bit order were asserted before covariance sampling. No borrowed correlations. Per-event conjunction predictions and residuals, period tension, mass function, companion minimum mass, orbital scale and central duration estimates follow. TIC properties and assumed companion radii are feasibility inputs, not measured dimensions. Two-disk limb-darkened models account for partial overlap; poor fits/grid edges prevent calibrated e sin omega or component posterior claims.

Ancillary log block 3: 568 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Other-conjunction windows and width/phase-grid limits follow. These are pointwise conditional template limits, not a uniform simultaneous confidence bound; coverage varies.

Ancillary log block 4: 8958 lines are preserved in linked text evidence and in the full archived report. Scientific prose and tables continue below.

Independent reduction and source attribution

Exact target and sector FITS identities were validated. This is a different pipeline using the same TESS pixels, not another observatory. Linear/quadratic baseline and background-sensitive depths are retained; aperture/PDCSAP depth differences reflect dilution and processing. TARS has no quality column.

One bounded Harvard multi-catalogue mirror probe timed out after batchG reported all IDIA9 requests timing out. ASAS-SN, SB9, WDS, Prsa, IJspeert and Kostov tables therefore remain unchecked in this fresh pass; failed service is not a negative match. VSX raw table sections were inspected; no target EB rows found. General web searches on the ten exact SIMBAD names plus eclipsing/binary found only unrelated results, not exact-target prior publications. This does not establish novelty or a complete bibliography.

Predictions and deciding next check

AtBTJD4344.32880: next primary~4359.49063; other conjunction~4372.26912. Photometric extrapolations are scheduling estimates, conditional on stationary orbit. For null secondary use Gaia phase uncertainty, not the single date.

Joint diluted light-curve/RV modelling to refine radii, flux ratio and small-e geometry.

Final adjudication: **CONFIRMED**. Six sharp primary events, independent TESS-SPOC, own Gaia covariance timing and target-centered pixel deficit establish an eclipsing target. The46.89arcsec neighbor is disfavored (residual0.961 vs target0.123). Missing other eclipse is geometrically feasible; limits are conditional.

Reproducibility: scripts and manifests retained in this batch. Original source audit completed before work; no source/paper edits or commits.

Lead control audit: {"median_primary_ppt": 71.38866728804093, "offphase_census_triggers": 0, "max_offphase_census_ppt": 0, "minimum_bg_regressed_depth_ratio": 0.9988502115682464}. Census trigger centers/durations can merge broad eclipse wings, especially253923749; they are not a calibrated blind-search catalog. VSX neighbor Gaia DR3 5647004382107259264 at47.04arcsec is ROT; it is not target prior EB classification.

R071. TIC 382423586

physical_verdict: CONFIRMED

novelty_status: uncatalogued within seven scoped catalogue checks; no exhaustive priority claim

completion: completed under current Conventions; limitations retained

next_check: Joint RV/eclipse characterization; retain Gaia period caveats.

Archived source: sanitized report text.

TIC 382423586: CONFIRMED

Repeated deep eclipses localized to the target, a period measured from raw flux and independent photometric extraction support a target eclipsing binary. Review completed under `../../../BRIEF.md`; characterization limitations below do not erase this evidence.

Raw QLP SAP_FLUX, QUALITY=0, representative local quadratic-plus-trapezoid fits: 3 accepted events in sectors [2, 30, 97]; depths 65.42 to 77.23 ppt, durations 6.12 to 6.16 h. Eclipse-derived period 13.25691311 d, epoch 1367.594964 BTJD; timing residual RMS 0.33 min. No precision period error inferred. Lead inspected the first/last raw event panels; repeat eclipse structure survives local baselines. Underlying individual times, depths, fit edges and method: `../../raw-evidence/raw-events.json`; full20-event panel: `../../raw-evidence/raw-event-panels.png`.

Independent TESS-SPOC sector 30 raw SAP_FLUX reproduces depths 73.47 ppt at the QLP event times. FITS TIC/sector and product URI were checked; QUALITY=0 where supplied. Product `mast:HLSP/tess-spoc/s0030/target/0000/0003/8242/3586/hlsp_tess-spoc_tess_phot_0000000382423586-s0030_tess_v1_lc.fits`, SHA256 `d94342da1017d5c445ea5f022d880f5592d05cf683eaea36d138df32623c8f45`. Fixed QLP shape; reported product errors are uninflated formal errors, with aperture/dilution differences retained. Same TESS photons, independent reduction.

Difference imaging: cached sector97, 4 events, deficit-target distance4.15arcsec and peak[8, 8] versus target pixel[8, 8]. Lead visually inspected target and neighbour maps. No Gaia neighbour within the tested60arcsec cone can supply the eclipse at its catalogue G flux under a total-eclipse upper bound. See `../../source-review.json` and original pixel receipts in `../../raw-evidence/382423586/`; PSF residual0.060 is descriptive and includes field contamination.

Exact Gaia DR3 source4726633469417138688: SB1 P=13.25607783 +/- 0.00116476d, e=0.2905, omega=172.09deg. Closest conjunctionA at first fitted epoch: observed-minus-Gaia+0.0990d, linear full-covariance error0.0979d. The eclipse period projected back near BTJD389 gives offset+0.0372d. Conditional duration feasibility: observed median6.13h is below the central crossing estimate10.51h using TIC R1=2.44413Rsun, M1=1.02Msun and minimum companion mass0.653Msun with a main-sequence radius approximation. Shorter grazing chords are feasible. This is a consistency check, not a unique geometry fit. See `../../gaia-geometry.json` for covariance assumptions and alternatives.

No target prior EB established in the seven scoped checks; coverage limited to recorded services, identifiers and catalogue versions. SIMBAD primary is SB*, Gaia DR3 EB has no exact row; VSX exact rows: `[]`; ASAS-SN exact rows: `[]`. Prsa, IJspeert and vetted Kostov tables3/4 have recorded original

five-arcsec negative checks; Kostov table2 candidates do not establish prior EB. Nearby catalogue variables are separate sources. Provenance and limits: `../../../shared-catalogues/coverage-matrix.csv` and README.

Representative events use the original search cycle counts, native cadence without integration, and local quadratic baselines. Depths/durations are conditional measurements, not precision stellar parameters. Two-event ephemerides have no empirical residual uncertainty. Colour, aperture throughput, unresolved companions and untested faint/distant sources limit localization; no calibrated centroid error is claimed.

Next check: joint RV/eclipse analysis with improved stellar dimensions; revisit Gaia orbit drift where noted.

Difference imaging: cached sector41, 12 events, deficit-target distance1.48arcsec and peak[7, 7] versus target pixel[7, 7]. Lead visually inspected target and neighbour maps. Capable neighbours: Gaia 2167438654485186176, separation40.9arcsec, required own loss60.6%, measured own-pixel fractional loss2.39%, deficit centroid44.9arcsec away; Gaia 2167438551405962880, separation44.9arcsec, required own loss93.6%, measured own-pixel fractional loss0.42%, deficit centroid48.0arcsec away. The disappearing light peaks at the target, spatially separate from these neighbours; neighbour-pixel losses alone are not treated as intrinsic deblended photometry. See `../../source-review.json` and original pixel receipts in `../../raw-evidence/195483879/`; PSF residual0.926 is descriptive and includes field contamination.

Exact Gaia DR3 source2167438585765915904: SB1 P=2.25736108 +/- 0.000145201d, e=0.0428, omega=159.55deg. Closest conjunctionA at first fitted epoch: observed-minus-Gaia-0.0461d, linear full-covariance error0.0863d. The eclipse period projected back near BTJD389 gives offset-0.0212d. Conditional duration feasibility: observed median2.40h is below the central crossing estimate3.79h using TIC R1=1.23819Rsun, M1=1Msun and minimum companion mass0.580Msun with a main-sequence radius approximation. Shorter grazing chords are feasible. This is a consistency check, not a unique geometry fit. See `../../gaia-geometry.json` for covariance assumptions and alternatives.

No target prior EB established in the seven scoped checks; coverage limited to recorded services, identifiers and catalogue versions. SIMBAD primary is SB*, Gaia DR3 EB has no exact row; VSX exact rows: `[]`; ASAS-SN exact rows: `[]`. Prsa, IJspeert and vetted Kostov tables3/4 have recorded original five-arcsec negative checks; Kostov table2 candidates do not establish prior EB. Nearby catalogue variables are separate sources. Provenance and limits: `../../../shared-catalogues/coverage-matrix.csv` and README.

Representative events use the original search cycle counts, native cadence without integration, and local quadratic baselines. Depths/durations are conditional measurements, not precision stellar parameters. Two-event ephemerides have no empirical residual uncertainty. Colour, aperture throughput, unresolved companions and untested faint/distant sources limit localization; no calibrated centroid error is claimed.

Next check: joint RV/eclipse analysis with improved stellar dimensions; revisit Gaia orbit drift where noted.

next_check: Joint RV/eclipse characterization; retain Gaia period caveats.

Archived source: sanitized report text.

TIC 414008363: CONFIRMED

Repeated deep eclipses localized to the target, a period measured from raw flux and independent photometric extraction support a target eclipsing binary. Review completed under `../../../BRIEF.md`; characterization limitations below do not erase this evidence.

Raw QLP SAP_FLUX, QUALITY=0, representative local quadratic-plus-trapezoid fits: 2 accepted events in sectors [91]; depths 78.79 to 79.39 ppt, durations 3.48 to 3.48 h. Eclipse-derived period 2.92040346 d, epoch 3778.236942 BTJD; timing residual RMS 0.00 min. No precision period error inferred. Lead inspected the first/last raw event panels; repeat eclipse structure survives local baselines. Underlying individual times, depths, fit edges and method: `../../raw-evidence/raw-events.json`; full20-event panel: `../../raw-evidence/raw-event-panels.png`.

Independent custom TESScut pixel extraction was rerun from `C:/Home/sky/data/sb1-scale-c3/vet414008363/tesscut_s091.fits` using the new eclipse period and duration. Six quality-filtered events at cycles [0, 1, 4, 5, 6, 7] reproduce 3x3 aperture depths 69.50, 68.83, 69.93, 68.00, 68.15, 68.02 ppt. WCS places the exact Gaia target inside the 15x15 cutout, sector91; file hash and identity checks are in `414008363-pixel-provenance.json`. This is a distinct pixel extraction from QLP, not a separate archive SPOC product. Direct TESS-SPOC91 returned404; inventory requests timed out.

Difference imaging: cached sector91, 6 events, deficit-target distance1.91arcsec and peak[7, 8] versus target pixel[7, 8]. Lead visually inspected target and neighbour maps. No Gaia neighbour within the tested60arcsec cone can supply the eclipse at its catalogue G flux under a total-eclipse upper bound. See `../../source-review.json` and original pixel receipts in `../../raw-evidence/414008363/`; PSF residual0.332 is descriptive and includes field contamination.

Exact Gaia DR3 source4330700736708121216: SB1 P=2.92041761 +/- 6.44376e-05d, e=0.0119, omega=6.94deg. Closest conjunctionA at first fitted epoch: observed-minus-Gaia-0.0073d, linear full-covariance error0.0731d. The eclipse period projected back near BTJD389 gives offset+0.0091d. Conditional duration feasibility: observed median3.48h is below the central crossing estimate5.49h using TIC R1=1.83895Rsun, M1=1.118Msun and minimum companion mass0.687Msun with a main-sequence radius approximation. Shorter grazing chords are feasible. This is a consistency check, not a unique geometry fit. See `../../gaia-geometry.json` for covariance assumptions and alternatives.

No target prior EB established in the seven scoped checks; coverage limited to recorded services, identifiers and catalogue versions. Raw QLP SAP_FLUX, QUALITY=0, representative local quadratic-plus-trapezoid fits: 6 accepted events in sectors [45, 46, 72]; depths 74.83 to 77.12 ppt, durations 3.26 to 3.34 h. Eclipse-derived period 4.68300741 d, epoch 2528.126165 BTJD; timing residual RMS 0.29 min. No precision period error inferred. Lead inspected the first/last raw event panels; repeat eclipse structure survives local baselines. Underlying individual times, depths, fit edges and method: `../../raw-evidence/raw-events.json`; full20-event panel: `../../raw-evidence/raw-event-panels.png`.

Independent SPOC sector 45 raw SAP_FLUX reproduces depths 72.52, 71.66 ppt at the QLP event times. FITS TIC/sector and product URI were checked; QUALITY=0 where supplied. Product `mast:TESS/product/tess2021310001228-s0045-0000000061106869-0216-s_lc.fits`, SHA256 `e9466ed93ee390da900622a909075619a203070b8b73a24ee19840fa3aef301c`. Fixed QLP shape; reported product errors are uninflated formal errors, with aperture/dilution differences retained. Same TESS photons, independent reduction.

Difference imaging: cached sector45, 5 events, deficit-target distance3.24arcsec and peak[7, 7] versus target pixel[7, 7]. Lead visually inspected target and neighbour maps. No Gaia neighbour within the tested60arcsec cone can supply the eclipse at its catalogue G flux under a total-eclipse upper bound. See `../../source-review.json` and original pixel receipts in `../../raw-evidence/61106869/`; PSF residual0.216 is descriptive and includes field contamination.

Exact Gaia DR3 source3888846561563641088: SB1 P=4.68303722 +/- 0.000287749d, e=0.0376, omega=293.95deg. Closest conjunctionA at first fitted epoch: observed-minus-Gaia-0.0042d, linear full-covariance error0.1482d. The eclipse period projected back near BTJD389 gives offset+0.0094d. Conditional duration feasibility: observed median3.30h is below the central crossing estimate3.77h using TIC R1=1.00162Rsun, M1=1.134Msun and minimum companion mass0.255Msun with a main-sequence radius approximation. Shorter grazing chords are feasible. This is a consistency check, not a unique geometry fit. See `../../gaia-geometry.json` for covariance assumptions and alternatives.

No target prior EB established in the seven scoped checks; coverage limited to recorded services, identifiers and catalogue versions. SIMBAD primary is SB*, Gaia DR3 EB has no exact row; VSX exact rows: `[]`; ASAS-SN exact rows: `[]`. Prsa, IJspeert and vetted Kostov tables3/4 have recorded original

five-arcsec negative checks; Kostov table2 candidates do not establish prior EB. Nearby catalogue variables are separate sources. Provenance and limits: `../../../shared-catalogues/coverage-matrix.csv` and README.

Representative events use the original search cycle counts, native cadence without integration, and local quadratic baselines. Depths/durations are conditional measurements, not precision stellar parameters. Two-event ephemerides have no empirical residual uncertainty. Colour, aperture throughput, unresolved companions and untested faint/distant sources limit localization; no calibrated centroid error is claimed.

Next check: joint RV/eclipse analysis with improved stellar dimensions; revisit Gaia orbit drift where noted.

R081. TIC 39478038

physical_verdict: CONFIRMED

novelty_status: uncatalogued within seven scoped catalogue checks; no exhaustive priority claim

completion: complete

next_check: See target report for limitations.

Archived source: sanitized report text.

TIC 39478038

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [12, 66, 93]; depths 76.03–81.24 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=9.503422557 d from event centres. Timing RMS=0.348 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the raw event panel.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 2.650 arcsec. All flux-capable catalogued neighbours have deficit centres closer to the target and own-pixel losses substantially below the losses required if they supplied the eclipse. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test.

Capable neighbour Gaia DR3 5977612444714736896: catalog separation 52.04 arcsec, required loss 90.51%, own-pixel loss 1.67%, deficit distance 50.92 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

TESS-SPOC sector 12 confirms event depths 68.59 ppt. Fixed QLP event shape with independently extracted SAP flux; uninflated formal depth errors (ppt): 0.293. FITS TIC/sector headers and padded TIC URI identity pass. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=9.503787906 d, difference -0.47 Gaia sigma. Closest edge-on conjunction A offset -0.04914 d versus linear full SB1 covariance error 0.11681 d; no significant timing contradiction. Observed median duration 5.73 h versus approximate central main-sequence feasibility 8.23 h; mass function 0.02867 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes.

Raw QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [14, 41, 81]; depths 95.47–100.16 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=4.086734477 d from event centres. Timing RMS=2.007 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the raw event panel.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 3.449 arcsec. All flux-capable catalogued neighbours have deficit centres closer to the target and own-pixel losses substantially below the losses required if they supplied the eclipse. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test. High PSF fractional residual is retained as a characterization limitation; attribution rests on the deficit peak and neighbour comparison, not a formal PSF likelihood. Lead inspected the cached three-panel image.

Capable neighbour Gaia DR3 1827076549435745536: catalog separation 36.21 arcsec, required loss 86.31%, own-pixel loss 0.55%, deficit distance 39.04 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

TESS-SPOC sector 14 confirms event depths 81.14 ppt. Fixed QLP event shape with independently extracted SAP flux; uninflated formal depth errors (ppt): 5.101. FITS TIC/sector headers and padded TIC URI identity pass. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=4.086494002 d, difference 1.63 Gaia sigma. Closest edge-on conjunction A offset 0.09940 d versus linear full SB1 covariance error 0.05200 d; no significant timing contradiction. Observed median duration 2.80 h versus approximate central main-sequence feasibility 4.29 h; mass function 0.05298 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes.

Archived source: sanitized report text.

TIC 443053687

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [6, 33, 87]; depths 125.63–132.67 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=5.591920047 d from event centres. Timing RMS=1.287 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the representative raw event panel; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 1.973 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test.

TESS-SPOC sector 6 confirms event depths 125.23, 125.83 ppt. Fixed QLP event shape with independently extracted SAP flux; uninflated formal depth errors (ppt): 0.524, 0.522. FITS TIC/sector headers and padded TIC URI identity pass. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=5.591797982 d, difference 0.61 Gaia sigma. Closest edge-on conjunction A offset 0.03493 d versus linear full SB1 covariance error 0.03655 d; timing differences and propagation limits are retained. Observed median duration 5.30 h versus approximate central main-sequence feasibility 7.10 h; mass function 0.12717 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Remeasured raw depths about 126-130 ppt exceed the queue search depth 92.6 ppt; raw measurements govern this review. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

Archived source: sanitized report text.

TIC 311147906

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 4 representative events in sectors [63, 99]; depths 71.96–94.69 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=14.335535574 d from event centres. Timing RMS=0.013 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the representative raw event panel; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 2.182 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test.

TESS-SPOC sector 63 confirms event depths 81.65, 81.31 ppt. Fixed QLP event shape with independently extracted SAP flux; uninflated formal depth errors (ppt): 0.185, 0.213. FITS TIC/sector headers and padded TIC URI identity pass. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=14.334909016 d, difference 0.23 Gaia sigma. Closest edge-on conjunction A offset -0.00243 d versus linear full SB1 covariance error 0.19770 d; timing differences and propagation limits are retained. Observed median duration 6.27 h versus approximate central main-sequence feasibility 7.56 h; mass function 0.04300 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. QLP representative depth changes from about 95 ppt in sector 63 to 72 ppt in sector 99; independent depth and localization establish the eclipses, while aperture/systematics or astrophysical depth variation require characterization. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

TIC 431535710

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 4 representative events in sectors [91, 92]; depths 101.05–102.62 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=5.063180122 d from event centres. Timing RMS=0.146 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the representative raw event panel; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 1.854 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test. High PSF fractional residual is retained as a characterization limitation; attribution rests on the deficit peak and neighbour comparison, not a formal PSF likelihood.

Independent TESScut pixel aperture extraction sector 91 confirms event depths 75.86, 75.22, 77.36, 79.65 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=5.063220685 d, difference -0.20 Gaia sigma. Closest edge-on conjunction A offset -0.05819 d versus linear full SB1 covariance error 0.12881 d; timing differences and propagation limits are retained. Observed median duration 3.36 h versus approximate central main-sequence feasibility 4.66 h; mass function 0.03480 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. Archived source: sanitized report text.

TIC 242199703

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [6, 33, 87]; depths 96.21–104.72 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=4.616750783 d from event centres. Timing RMS=0.479 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the representative raw event panel; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 3.353 arcsec. All flux-capable catalogued neighbours have deficit centres closer to the target and own-pixel losses substantially below the losses required if they supplied the eclipse. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test. High PSF fractional residual is retained as a characterization limitation; attribution rests on the deficit peak and neighbour comparison, not a formal PSF likelihood. Lead inspected the cached three-panel image.

Capable neighbour Gaia DR3 3118063076268995712: catalog separation 37.46 arcsec, required loss 32.20%, own-pixel loss 1.47%, deficit distance 38.24 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

TESS-SPOC sector 6 confirms event depths 79.32 ppt. Fixed QLP event shape with independently extracted SAP flux; uninflated formal depth errors (ppt): 0.369. FITS TIC/sector headers and padded TIC URI identity pass. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=4.616731440 d, difference 0.13 Gaia sigma. Closest edge-on conjunction A offset 0.02935 d versus linear full SB1 covariance error 0.04608 d; timing differences and propagation limits are retained. Observed median duration 3.71 h versus approximate central main-sequence feasibility 4.59 h; mass function 0.02597 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. R098. TIC 186100980

physical_verdict: PROBABLE

novelty_status: uncatalogued; seven-group coverage recovered; dated tier reconciliation 2026-10-30

completion: complete

next_check: Repeated eclipses secure; host attribution/check unresolved. See dated tier reconciliation and unchanged historical report.

Archived source: sanitized report text.

TIC 186100980

PLAUSIBLE. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [35, 62, 89]; depths 100.96–105.42 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=3.946189659 d from event centres. Timing RMS=0.438 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the representative raw event panel; sector-dependent aperture dilution and baseline changes remain in the depths.

Seven stacked sector88 eclipses put the deficit in the target blend. A flux-capable Gaia neighbour at 4.35 arcsec needs 81.77% own loss; the deficit is 3.37 arcsec from that neighbour and 4.93 arcsec from the target. Both share the TESS resolution element. Own-pixel fractional loss 8.71% is mixed flux and cannot exclude an eclipsing neighbour. Lead inspected the cached image; source attribution remains scientifically ambiguous without resolved photometry or calibrated subpixel source fitting. The 42.33 arcsec capable neighbour is spatially disfavoured.

Capable neighbour Gaia DR3 5641174256061047808: catalog separation 4.35 arcsec, required loss 81.77%, own-pixel loss 8.71%, deficit distance 3.37 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Capable neighbour Gaia DR3 5641174462219480448: catalog separation 42.33 arcsec, required loss 72.98%, own-pixel loss 3.88%, deficit distance 40.97 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

TESS-SPOC sector 35 confirms event depths 85.19, 85.01 ppt. Fixed QLP event shape with independently extracted SAP flux; uninflated formal depth errors (ppt): 0.36, 0.343. FITS TIC/sector headers and padded TIC URI identity pass. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=3.946208831 d, difference -0.20 Gaia sigma. Closest edge-on conjunction A offset -0.03211 d versus linear full SB1 covariance error 0.04375 d; timing differences and propagation limits are retained. Observed median duration 3.46 h versus approximate central main-sequence feasibility 4.56 h; mass function 0.04265 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec.

Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Scientific status: repeated eclipses are established in the blend and match the target SB1 orbit, which favours the target. However the capable 4.35 arcsec neighbour is unresolved in these data; this is an attribution ambiguity, not incomplete execution. Resolved eclipse photometry or calibrated source separation would decide it. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [18, 25, 85]; depths 98.61–105.41 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=6.328025502 d from event centres. Timing RMS=1.418 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the representative raw event panel; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 2.190 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test.

TESS-SPOC sector 18 confirms event depths 95.47, 94.93 ppt. Fixed QLP event shape with independently extracted SAP flux; uninflated formal depth errors (ppt): 0.405, 0.274. FITS TIC/sector headers and padded TIC URI identity pass. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=6.328371893 d, difference -1.92 Gaia sigma. Closest edge-on conjunction A offset -0.07042 d versus linear full SB1 covariance error 0.03119 d; timing differences and propagation limits are retained. Observed median duration 6.95 h versus approximate central main-sequence feasibility 9.04 h; mass function 0.08577 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

R101. TIC 353848852

physical_verdict: CONFIRMED

novelty_status: uncatalogued within seven scoped catalogue checks; no exhaustive priority claim

completion: complete

next_check: See target report for limitations.

Archived source: sanitized report text.

TIC 353848852

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 2 representative events in sectors [17, 57]; depths 101.15–101.77 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=19.123018802 d from event centres. Timing RMS=0.000 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the raw event panel.

Cached eclipse deficit peaks at the target pixel, offset 1.248 arcsec. No Gaia G-band flux-capable neighbour is recorded within 60 arcsec. Centroid displacement is descriptive; G/TESS band differences, unresolved or uncatalogued blends and PSF modelling limit this test. High PSF residual limits characterization; attribution uses the deficit peak and neighbour comparison.

Independent TESScut pixel aperture extraction sector 17 confirms event depths 97.87 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=19.119397021 d, difference 1.70 Gaia sigma. Closest edge-on conjunction A offset 0.18004 d versus linear full SB1 covariance error 0.17020 d; no significant timing contradiction. Observed median duration 6.17 h versus approximate central main-sequence feasibility 6.67 h; mass function 0.03300 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix status is no identified prior EB; coverage is yes. See the target-specific matches in catalogue-review.json. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes.

Independent measurements use core medians rather than the QLP trapezoid depth, so numerical equality of the depths is not assumed. Product-inventory failures are preserved; this check uses an independent aperture extraction, not a separately delivered pipeline product.

Separate central open-release comparison found no exact Gaia/TIC overlap in the available track3/dossier tables; overlap with the embargoed 93-system release is unknown. This is not an additional EB gate. See ../shared-catalogues/README.md.

R102. TIC 432482170

CONFIRMED. Execution: complete. Scoped novelty: known prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [17, 57, 84]; depths 109.83–115.23 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=3.587543413 d from event centres. Timing RMS=1.194 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the raw event panel.

Cached eclipse deficit peaks at the target pixel, offset 4.845 arcsec. No Gaia G-band flux-capable neighbour is recorded within 60 arcsec. Centroid displacement is descriptive; G/TESS band differences, unresolved or uncatalogued blends and PSF modelling limit this test.

Independent TESScut pixel aperture extraction sector 57 confirms event depths 97.66, 98.10, 95.85, 96.31, 97.70, 99.30, 98.01 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=3.587429939 d, difference 1.17 Gaia sigma. Closest edge-on conjunction A offset 0.00425 d versus linear full SB1 covariance error 0.03504 d; no significant timing contradiction. Observed median duration 3.74 h versus approximate central main-sequence feasibility 4.62 h; mass function 0.08731 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix status is known prior EB; coverage is yes. See the target-specific matches in catalogue-review.json. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes.

Prior-EB identification: exact TIC/Gaia ASAS-SN EA J000026.84+393855.4, separation 0.28 arcsec, catalogue period 3.5877 d. This is a physically reviewed known EB, not an uncatalogued discovery.

Independent measurements use core medians rather than the QLP trapezoid depth, so numerical equality of the depths is not assumed. Product-inventory failures are preserved; this check uses an independent aperture extraction, not a separately delivered pipeline product.

Separate central open-release comparison found no exact Gaia/TIC overlap in the available track3/dossier tables; overlap with the embargoed 93-system release is unknown. This is not an additional EB gate. See ../shared-catalogues/README.md.

R103. TIC 364120441

physical_verdict: CONFIRMED

novelty_status: uncatalogued within seven scoped catalogue checks; no exhaustive priority claim

completion: complete

next_check: See target report for limitations.

Archived source: sanitized report text.

TIC 364120441

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [16, 57, 86]; depths 100.73–104.96 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=9.320238676 d from event centres. Timing RMS=0.229 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the raw event panel.

Cached eclipse deficit peaks at the target pixel, offset 3.013 arcsec. The capable neighbour is spatially distinct, farther from the eclipse deficit, with own-pixel fractional loss much below that needed to supply the eclipse. Centroid displacement is descriptive; G/TESS band differences, unresolved or uncatalogued blends and PSF modelling limit this test. High PSF residual limits characterization; attribution uses the deficit peak and neighbour comparison. Lead inspected the cached difference-image panel.

Capable neighbour Gaia DR3 2276488904907517312: catalog separation 31.62 arcsec, required loss 15.34%, own-pixel loss 0.39%, deficit distance 35.25 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Independent TESScut pixel aperture extraction sector 20 confirms event depths 37.71, 35.73, 35.54 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=9.320765417 d, difference -0.78 Gaia sigma. Closest edge-on conjunction A offset -0.02559 d versus linear full SB1 covariance error 0.11851 d; no significant timing contradiction. Observed median duration 5.51 h versus approximate central main-sequence feasibility 6.15 h; mass function 0.03363 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix status is no identified prior EB; coverage is yes. See the target-specific matches in catalogue-review.json. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes.

The independent sector-20 aperture depths are only 35.5–37.7 ppt versus about 101 ppt QLP depths in sectors16/86. The reductions show repeated eclipses at matching phases but do not agree in depth. Aperture/sector dilution, systematics and differing measurement definitions are possible contributors; no cause is established. Core-median depths can underestimate the deepest point of V-shaped events. The spatial deficit test, rather than assumed equal depths, supplies attribution evidence.

Independent measurements use core medians rather than the QLP trapezoid depth, so numerical equality of the depths is not assumed. Product-inventory failures are preserved; this check uses an independent aperture extraction, not a separately delivered pipeline product.

Bounded same-sector check: sector20 QLP core depths103.37,98.69,95.98ppt versus3x3 depths37.71,35.73,35.54ppt at the same primary epochs. Pixel1x1 depths69.24–75.92ppt and5x5 depths26.59–27.72ppt demonstrate strong aperture dependence. The G10.43 neighbour is about2.07 times the G flux of the G11.22 target, sufficient to make this dilution plausible. Deficit target/neighbour distances are3.01/35.25arcsec. See DEPTH-SANITY-364120441.md and depth-sanity-364120441.json for counts, provenance and limitations; source/timing evidence supports the target.

Separate central open-release comparison found no exact Gaia/TIC overlap in the available track3/dossier tables; overlap with the embargoed 93-system release is unknown. This is not an additional EB gate. See ../shared-catalogues/README.md.

R104. TIC 100249241

Archived source: sanitized report text.

TIC 39069184

PLAUSIBLE. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [1, 29, 96]; depths 209.62–266.92 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=3.350034558 d from event centres. Timing RMS=0.331 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the raw event panel.

Cached eclipse deficit peaks at the target pixel, offset 1.448 arcsec. A flux-capable Gaia neighbour is only 2.21 arcsec away (0.105 TESS pixel). The deficit is nominally closer to the target, but centroid errors are uncalibrated and own-pixel loss mixes the two sources; attribution remains ambiguous at this separation. This prevents a target-specific confirmation despite strong repeated eclipses. Centroid displacement is descriptive; G/TESS band differences, unresolved or uncatalogued blends and PSF modelling limit this test. Lead inspected the cached difference-image panel.

Capable neighbour Gaia DR3 4704376708370040960: catalog separation 2.21 arcsec, required loss 68.27%, own-pixel loss 13.07%, deficit distance 3.58 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Independent TESScut pixel aperture extraction sector 28 confirms event depths 178.03, 171.18, 180.40, 175.63, 178.57, 170.92 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=3.349923348 d, difference 0.91 Gaia sigma. Closest edge-on conjunction A offset 0.03245 d versus linear full SB1 covariance error 0.03525 d; no significant timing contradiction. Observed median duration 3.64 h versus approximate central main-sequence feasibility 4.61 h; mass function 0.11861 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix status is no identified prior EB; coverage is yes. See the target-specific matches in catalogue-review.json. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes.

Physical verdict is PLAUSIBLE because source attribution to the Gaia SB1 remains unresolved against the flux-capable 2.21 arcsec neighbour. Execution is complete; the limitation is scientific ambiguity.

Independent measurements use core medians rather than the QLP trapezoid depth, so numerical equality of the depths is not assumed. Product-inventory failures are preserved; this check uses an independent aperture extraction, not a separately delivered pipeline product.

Separate central open-release comparison found no exact Gaia/TIC overlap in the available track3/dossier tables; overlap with the embargoed 93-system release is unknown. This is not an additional EB gate. See ../shared-catalogues/README.md.

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 3 representative events in sectors [3, 30]; depths 116.81–120.98 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=15.834577984 d from event centres. Timing RMS=0.286 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the raw event panel.

Cached eclipse deficit peaks at the target pixel, offset 5.062 arcsec. No Gaia G-band flux-capable neighbour is recorded within 60 arcsec. Centroid displacement is descriptive; G/TESS band differences, unresolved or uncatalogued blends and PSF modelling limit this test.

Independent TESScut pixel aperture extraction sector 30 confirms event depths 98.90, 98.12 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=15.836217392 d, difference -0.68 Gaia sigma. Closest edge-on conjunction A offset -0.17780 d versus linear full SB1 covariance error 0.15408 d; no significant timing contradiction. Observed median duration 6.28 h versus approximate central main-sequence feasibility 9.89 h; mass function 0.13737 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix status is no identified prior EB; coverage is yes. See the target-specific matches in catalogue-review.json. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes.

Independent measurements use core medians rather than the QLP trapezoid depth, so numerical equality of the depths is not assumed. Product-inventory failures are preserved; this check uses an independent aperture extraction, not a separately delivered pipeline product.

Separate central open-release comparison found no exact Gaia/TIC overlap in the available track3/dossier tables; overlap with the embargoed 93-system release is unknown. This is not an additional EB gate. See ../shared-catalogues/README.md.

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [11, 100, 102]; depths 106.83–116.33 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=7.393782739 d from event centres. Timing RMS=1.262 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The lead inspected the raw event panel.

Cached eclipse deficit peaks at the target pixel, offset 3.242 arcsec. No Gaia G-band flux-capable neighbour is recorded within 60 arcsec. Centroid displacement is descriptive; G/TESS band differences, unresolved or uncatalogued blends and PSF modelling limit this test. High PSF residual limits characterization; attribution uses the deficit peak and neighbour comparison.

Independent TESScut pixel aperture extraction sector 65 confirms event depths 100.85, 100.49, 99.68, 99.76 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=7.393323173 d, difference 0.90 Gaia sigma. Closest edge-on conjunction A offset 0.09756 d versus linear full SB1 covariance error 0.09165 d; no significant timing contradiction. Observed median duration 9.54 h versus approximate central main-sequence feasibility 10.34 h; mass function 0.14891 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix status is no identified prior EB; coverage is yes. See the target-specific matches in catalogue-review.json. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes.

The 0.20 arcsec VSX VAR entry GDS_J1400595-632825 may be the target; exact ASAS-SN ROT: and VAR do not classify an EB. Retain the identity caveat without treating it as prior-EB evidence.

Independent measurements use core medians rather than the QLP trapezoid depth, so numerical equality of the depths is not assumed. Product-inventory failures are preserved; this check uses an independent aperture extraction, not a separately delivered pipeline product.

Separate central open-release comparison found no exact Gaia/TIC overlap in the available track3/dossier tables; overlap with the embargoed 93-system release is unknown. This is not an additional EB gate. See ../shared-catalogues/README.md.

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 4 representative events in sectors [33, 87]; depths 236.22 to 260.77 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=5.287442298 d from event centres. Timing RMS=0.316 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 3.365 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test.

Independent TESScut pixel aperture extraction sector 33 confirms event depths 176.06, 185.78, 183.10, 183.72 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=5.287644303 d, difference -0.63 Gaia sigma. Closest edge-on conjunction A offset -0.08329 d versus linear full SB1 covariance error 0.05779 d; timing differences and propagation limits are retained. Observed median duration 4.08 h versus approximate central main-sequence feasibility 6.22 h; mass function 0.12471 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Remeasured QLP depths 236-261 ppt exceed the 114 ppt queue search depth. Independent sector 33 target-aperture core depths are about

176-186 ppt, while the separately retained TESS-SPOC sector 33 fit is about 207 ppt. Different apertures, estimator and dilution affect depth; the repeated deep eclipse is established and no equality of these depth estimators is assumed.

Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

R116. TIC 140802498

physical_verdict: CONFIRMED

novelty_status: uncatalogued within seven scoped catalogue checks; no exhaustive priority claim

completion: complete

next_check: See target report for limitations.

Archived source: sanitized report text.

TIC 140802498

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [1, 37, 98]; depths 108.50 to 132.20 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=3.962811291 d from event centres. Timing RMS=0.173 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 1.864 arcsec. The deficit centre is closer to the target than the flux-capable catalogued neighbours; own-pixel losses include mixed source light and are supporting spatial diagnostics only. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test. Lead inspected the cached three-panel image. A bounded repeatability test of the cached sector 97 cutout places seven-event half-stack deficits 3.12/0.77 arcsec from the target versus 12.06/11.36 arcsec from the capable neighbour. Individual event deficits stay nearer the target. Shifted empirical out-of-eclipse template fractional residual is 0.159 at the target versus 0.494 at the neighbour; the template is blended and this is a diagnostic, not a formal PRF likelihood. These repeated spatial comparisons identify the target as the source to the available TESS resolution. The shared rounded pixel and mixed own-pixel flux alone were not used as exclusion evidence.

Capable neighbour Gaia DR3 4649917107185561856: catalog separation 11.64 arcsec, required loss 88.71%, own-pixel loss 10.53%, deficit distance 11.64 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Independent TESScut pixel aperture extraction sector 97 confirms event depths 94.04, 93.96, 93.72, 101.08, 94.87, 95.04, 94.49, 95.15, 95.87, 97.47, 91.37, 98.83, 96.39, 94.39 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=3.962872501 d, difference -0.54 Gaia sigma. Closest edge-on conjunction A offset -0.02413 d versus linear full SB1 covariance error 0.02905 d; timing differences and propagation limits are retained. Observed median duration 4.10 h versus approximate central main-sequence feasibility 6.09

h; mass function 0.11211 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. TIC 4374712

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 7 representative events in sectors [20, 44, 45, 46, 71]; depths 119.97 to 126.63 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=16.125545364 d from event centres. Timing RMS=2.142 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 3.950 arcsec. The deficit centre is closer to the target than the flux-capable catalogued neighbours; own-pixel losses include mixed source light and are supporting spatial diagnostics only. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test. High PSF fractional residual is retained as a characterization limitation; attribution rests on the deficit peak and neighbour comparison, not a formal PSF likelihood. Lead inspected the cached three-panel image.

Capable neighbour Gaia DR3 881672952403795712: catalog separation 43.46 arcsec, required loss 88.67%, own-pixel loss 2.04%, deficit distance 43.37 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Independent TESScut pixel aperture extraction sector 45 confirms event depths 110.63, 110.33 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=16.127328842 d, difference -0.73 Gaia sigma. Closest edge-on conjunction A offset -0.24394 d versus linear full SB1 covariance error 0.23968 d; timing differences and propagation limits are retained. Observed median duration 5.10 h versus approximate central main-sequence feasibility 5.38 h; mass function 0.03454 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec.

Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. TIC 188085904

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [9, 90, 100]; depths 108.34 to 124.04 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=7.126225729 d from event centres. Timing RMS=1.951 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 2.683 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test. High PSF fractional residual is retained as a characterization limitation; attribution rests on the deficit peak and neighbour comparison, not a formal PSF likelihood.

Independent TESScut pixel aperture extraction sector 63 confirms event depths 100.24, 100.49, 100.61, 100.90 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=7.125616212 d, difference 1.32 Gaia sigma. Closest edge-on conjunction A offset 0.06247 d versus linear full SB1 covariance error 0.08792 d; timing differences and propagation limits are retained. Observed median duration 8.55 h versus approximate central main-sequence feasibility 10.69 h; mass function 0.13068 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

TIC 45006630

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [12, 99, 103]; depths 119.63 to 136.51 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=5.262707767 d from event centres. Timing RMS=2.709 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached difference-image deficit peaks at the target pixel; target/deficit distance 6.552 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; G/TESS band differences, uncatalogued blends and PSF modelling limit the test. High PSF fractional residual is retained as a characterization limitation; attribution rests on the deficit peak and neighbour comparison, not a formal PSF likelihood.

Independent TESScut pixel aperture extraction sector 38 confirms event depths 119.54, 119.91, 120.42, 121.88, 123.00 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=5.263085637 d, difference -1.77 Gaia sigma. Closest edge-on conjunction A offset -0.12775 d versus linear full SB1 covariance error 0.05735 d; timing differences and propagation limits are retained. Observed median duration 4.98 h versus approximate central main-sequence feasibility 5.93 h; mass function 0.05140 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. The conjunction difference is 2.23 times the linear covariance error. Together with the photometric/Gaia period agreement, localized repeated

eclipses and independent reduction, this is retained as a moderate timing tension and characterization limitation, rather than a demonstrated orbit contradiction.

Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

TIC 90563464

CONFIRMED. Full review execution: complete. Scoped novelty: no identified prior EB.

Raw repetition and eclipse period: QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [13, 93, 104], fitted depths 107.72-128.26 ppt. A quadratic local baseline plus trapezoid derives P=15.234218781 d from event centres, timing RMS 2.969 min. Fits use native cadence without exposure integration; timing fits are unweighted and conditional on search cycle counts, without a fitted uncertainty. A two-event zero residual is algebraic, not a precision claim. A fresh GPT-6.1 Terra helper reviewed the raw repetitions and independent reduction; see raw-evidence/rawhelper-summary.md and raw-evidence/pixel-independent-results.json.

Source attribution: Cached eclipse deficit peaks at the target pixel, offset 3.775 arcsec. No Gaia G-band flux-capable neighbour is recorded within 60 arcsec. Centroid displacements are descriptive; G/TESS band differences, uncatalogued or unresolved blends and PSF modelling limit the test.

Independent reduction: Independent TESScut pixel aperture extraction, sector 66, repeats eclipse depths 125.17, 124.73 ppt. Custom target aperture extraction of the same TESS photons supplies an independent reduction, not an independent observation or a SPOC product. Its local baseline/core medians and aperture dilution need not equal QLP trapezoid depths. Product/cutout identity, method, measurements and SHA256 are in raw-evidence/independent-results.json. Product-inventory failures are preserved, not treated as negative observations.

Gaia orbit geometry: SB1 P=15.234704142 d, photometric difference -0.21 Gaia sigma. Closest edge-on conjunction A offset -0.03162 d versus full SB1 covariance linear error 0.17364 d. Neither period nor conjunction reveals a strong contradiction. Observed median duration 7.33 h versus approximate central main-sequence feasibility 9.08 h; mass function 0.09958 solar masses. This is an orbit feasibility check, not fitted inclination, stellar radii or a unique geometry. Linear propagation may be approximate for nearly circular orbits; covariance order and assumptions are preserved in gaia_geometry.py.

Novelty: seven-scope central matrix reports no identified prior EB; coverage yes. Exact IDs and neighbours are separated in catalogue-review.json. SIMBAD SB* and ROT/VAR do not classify an EB; Kostov table2 is unvetted. Historical five-arcsec batteries retain condensed receipts; VSX/ASAS-SN cones are 60 arcsec. Alternate identities and catalogue versions limit this scoped result. Separate open-release comparison found no exact Gaia/TIC overlap in available tables; the embargoed 93-system release overlap is unknown and is not an additional EB gate. See ../shared-catalogues/README.md.

Next deciding test: No unresolved physical veto; resolved multiband eclipse photometry would improve dilution and radii.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, raw-evidence/independent-results.json, source-review.json, gaia-geometry.json, catalogue-review.json, lead-input-provenance.json and MANIFEST-SHA256.json.

CONFIRMED. Full review execution: complete. Scoped novelty: no identified prior EB.

Raw repetition and eclipse period: QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [12, 66, 103], fitted depths 116.55-137.57 ppt. A quadratic local baseline plus trapezoid derives P=11.027857969 d from event centres, timing RMS 1.337 min. Fits use native cadence without exposure integration; timing fits are unweighted and conditional on search cycle counts, without a fitted uncertainty. A two-event zero residual is algebraic, not a precision claim. A fresh GPT-6.1 Terra helper reviewed the raw repetitions and independent reduction; see raw-evidence/rawhelper-summary.md and raw-evidence/pixel-independent-results.json.

Source attribution: Cached eclipse deficit peaks at the target pixel, offset 5.919 arcsec. The G-band flux-capable neighbour is 43.24 arcsec from the target and 50.58 arcsec from the eclipse deficit; the disappearing source is localized near the target rather than that neighbour. The field is crowded; faint neighbours and colour-dependent flux limits remain caveats. Centroid displacements are descriptive; G/TESS band differences, uncatalogued or unresolved blends and PSF modelling limit the test. The lead inspected the cached difference-image panel.

Flux-capable Gaia DR3 5930552522426138880: separation 43.24 arcsec, required eclipse loss 39.53%, own-pixel loss 0.29%, deficit distance 50.58 arcsec. Own-pixel flux is mixed and does not alone exclude contamination.

Independent reduction: TESS-SPOC, sector 12, repeats eclipse depths 124.73 ppt. The separate archived light-curve product uses a fixed QLP-measured event shape; the template ties timing/shape but not the independent flux extraction. Product/cutout identity, method, measurements and SHA256 are in raw-evidence/independent-results.json. Product-inventory failures are preserved, not treated as negative observations.

Gaia orbit geometry: SB1 P=11.028952113 d, photometric difference -0.82 Gaia sigma. Closest edge-on conjunction A offset -0.12059 d versus full SB1 covariance linear error 0.12664 d. Neither period nor conjunction reveals a strong contradiction. Observed median duration 6.55 h versus approximate central main-sequence feasibility 9.15 h; mass function 0.14115 solar masses. This is an orbit feasibility check, not fitted inclination, stellar radii or a unique geometry. Linear propagation may be approximate for nearly circular orbits; covariance order and assumptions are preserved in gaia_geometry.py.

Novelty: seven-scope central matrix reports no identified prior EB; coverage yes. Exact IDs and neighbours are separated in catalogue-review.json. SIMBAD SB* and ROT/VAR do not classify an EB; Kostov table2 is unvetted. Historical five-arcsec batteries retain condensed receipts; VSX/ASAS-SN

cones are 60 arcsec. Alternate identities and catalogue versions limit this scoped result. Separate open-release comparison found no exact Gaia/TIC overlap in available tables; the embargoed 93-system release overlap is unknown and is not an additional EB gate. See ../shared-catalogues/README.md.

Raw repetition and eclipse period: QLP SAP_FLUX with QUALITY=0 yields 2 representative events in sectors [80], fitted depths 141.79-142.27 ppt. A quadratic local baseline plus trapezoid derives P=5.327671750 d from event centres, timing RMS 0.000 min. Fits use native cadence without exposure integration; timing fits are unweighted and conditional on search cycle counts, without a fitted uncertainty. A two-event zero residual is algebraic, not a precision claim. A fresh GPT-6.1 Terra helper reviewed the raw repetitions and independent reduction; see raw-evidence/rawhelper-summary.md and raw-evidence/pixel-independent-results.json.

Source attribution: Cached eclipse deficit peaks at the target pixel, offset 2.097 arcsec. No Gaia G-band flux-capable neighbour is recorded within 60 arcsec. The exact ASAS-SN ROT: identity and 0.80 arcsec VSX VAR entry are not prior-EB types. Nearby VSX E entries at 14.92, 40.16 and 58.55 arcsec identify distinct Gaia sources with periods 1.29114, 0.307656 and 6.9854 d; none is G-band flux-capable in the cached 60-arcsec source check, and their periods differ from the target primary eclipse period. Centroid displacements are descriptive; G/TESS band differences, uncatalogued or unresolved blends and PSF modelling limit the test. The lead inspected the cached difference-image panel.

Nearby catalogue EB Gaia DR3 4251816451161098880: G=19.581, required fractional flux loss 363.65 (greater than unity, hence not G-band flux-capable).

Nearby catalogue EB Gaia DR3 4251816554240317568: G=19.160, required fractional flux loss 246.72 (greater than unity, hence not G-band flux-capable).

Nearby catalogue EB Gaia DR3 4251813599322538112: G=16.798, required fractional flux loss 28.13 (greater than unity, hence not G-band flux-capable).

Independent reduction: TARS, sector 80, repeats eclipse depths 131.86, 117.63 ppt. The separate archived light-curve product uses a fixed QLP-measured event shape; the template ties timing/shape but not the independent flux extraction. Product/cutout identity, method, measurements and SHA256 are in raw-evidence/independent-results.json. Product-inventory failures are preserved, not treated as negative observations.

Gaia orbit geometry: SB1 P=5.327763075 d, photometric difference -0.32 Gaia sigma. Closest edge-on conjunction A offset -0.08342 d versus full SB1 covariance linear error 0.19387 d. Neither period nor conjunction reveals a strong contradiction. Observed median duration 4.12 h versus approximate central main-sequence feasibility 6.16 h; mass function 0.14231 solar masses. This is an orbit feasibility check, not fitted inclination, stellar radii or a unique geometry. Linear propagation may be approximate for nearly circular orbits; covariance order and assumptions are preserved in gaia_geometry.py.

Novelty: seven-scope central matrix reports no identified prior EB; coverage yes. Exact IDs and neighbours are separated in catalogue-review.json. SIMBAD SB* and ROT/VAR do not classify an EB; Kostov table2 is unvetted. Historical five-arcsec batteries retain condensed receipts; VSX/ASAS-SN cones are 60 arcsec. Alternate identities and catalogue versions limit this scoped result. Separate open-release comparison found no exact Gaia/TIC overlap in available tables; the embargoed 93-system release overlap is unknown and is not an additional EB gate. See ../shared-catalogues/README.md.

Next deciding test: No unresolved physical veto; resolved multiband eclipse photometry would improve dilution and radii.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, raw-evidence/independent-results.json, source-review.json, gaia-geometry.json, catalogue-review.json, lead-input-provenance.json and MANIFEST-SHA256.json.

Bounded depth check in sector80: four matching primary epochs yield QLP core depths 123.73-126.43 ppt versus 97.84-99.23 ppt in the independent 3x3 extraction. Pixel 1x1 depths 106.81-112.03 and 5x5 depths 77.13-78.90 ppt establish aperture dependence in this crowded field; QLP deepest-three depths are 146.89-149.03 ppt. The TARS independent product gives 131.86 and 117.63 ppt with fixed QLP shapes; its QUALITY column is absent and the formal errors omit systematics. These are consistent repeated eclipses but not identical depth estimates; dilution and reduction differences remain characterization limitations. See depth-sanity-162075402.json. Primary period is 5.327672 d; a half-period alias can arise from secondary eclipses and does not replace the full primary repetition.

completion: complete

next_check: See target report for limitations.

Archived source: sanitized report text.

TIC 417917895

CONFIRMED. Full review execution: complete. Scoped novelty: no identified prior EB.

Raw repetition and eclipse period: QLP SAP_FLUX with QUALITY=0 yields 4 representative events in sectors [14, 22, 75], fitted depths 144.74-147.92 ppt. A quadratic local baseline plus trapezoid derives P=15.975834079 d from event centres, timing RMS 2.929 min. Fits use native cadence without exposure integration; timing fits are unweighted and conditional on search cycle counts, without a fitted uncertainty. A two-event zero residual is algebraic, not a precision claim. A fresh GPT-6.1 Terra helper reviewed the raw repetitions and independent reduction; see raw-evidence/rawhelper-summary.md and raw-evidence/pixel-independent-results.json.

Source attribution: Cached eclipse deficit peaks at the target pixel, offset 3.044 arcsec. The flux-capable neighbour is 12.43 arcsec away, 14.35 arcsec from the stacked deficit. A bounded repeatability check using the two separate cached sector-15 events gives target offsets 3.02 and 3.17 arcsec versus neighbour offsets 13.90 and 14.81 arcsec. Shifting the empirical blended out-of-eclipse template to target versus neighbour gives fractional residuals 0.128 versus 0.595; this descriptive shape diagnostic favours the target. Own-pixel losses are mixed and do not alone exclude the neighbour. This supports target attribution without assigning a calibrated centroid significance. See raw-evidence/417917895/source_repeatability.json. Centroid displacements are descriptive; G/TESS band differences, uncatalogued or unresolved blends and PSF modelling limit the test. The lead inspected the cached difference-image panel.

Flux-capable Gaia DR3 1584822355036510720: separation 12.43 arcsec, required eclipse loss 91.67%, own-pixel loss 10.46%, deficit distance 14.35 arcsec. Own-pixel flux is mixed and does not alone exclude contamination.

Independent reduction: Independent TESScut pixel aperture extraction, sector 15, repeats eclipse depths 105.16, 101.90 ppt. Custom target aperture extraction of the same TESS photons supplies an independent reduction, not an independent observation or a SPOC product. Its local baseline/core medians and aperture dilution need not equal QLP trapezoid depths. Product/cutout identity, method, measurements and SHA256 are in raw-evidence/independent-results.json. Product-inventory failures are preserved, not treated as negative observations.

Gaia orbit geometry: SB1 P=15.979756207 d, photometric difference -1.96 Gaia sigma. Closest edge-on conjunction B offset -0.30425 d versus full SB1 covariance linear error 0.20427 d. Neither period nor conjunction reveals a strong contradiction. Observed median duration 5.78 h versus approximate

central main-sequence feasibility 8.67 h; mass function 0.26218 solar masses. This is an orbit feasibility check, not fitted inclination, stellar radii or a unique geometry. Linear propagation may be approximate for nearly circular orbits; covariance order and assumptions are preserved in gaia_geometry.py.

Novelty: seven-scope central matrix reports no identified prior EB; coverage yes. Exact IDs and neighbours are separated in catalogue-review.json. SIMBAD SB* and ROT/VAR do not classify an EB; Kostov table2 is unvetted. Historical five-arcsec batteries retain condensed receipts; VSX/ASAS-SN cones are 60 arcsec. Alternate identities and catalogue versions limit this scoped result. Separate open-release comparison found no exact Gaia/TIC overlap in available tables; the embargoed 93-system release overlap is unknown and is not an additional EB gate. See ../shared-catalogues/README.md.

Next deciding test: No unresolved physical veto; resolved multiband eclipse photometry would improve dilution and radii.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, raw-evidence/independent-results.json, source-review.json, gaia-geometry.json, catalogue-review.json, lead-input-provenance.json and MANIFEST-SHA256.json.

Bounded depth check: same sector-15 event core medians are 131.30/127.68 ppt in QLP versus 105.16/101.90 ppt in the 3x3 extraction; the deepest-three estimates are 147.72/146.85 versus 117.92/116.99 ppt. Pixel 1x1, 3x3 and 5x5 core ranges are 101.67-107.81, 101.90-105.16 and 100.31-103.18 ppt. A real reduction-dependent difference remains after matching sector and estimator; its cause is not established. Both dips repeat with the correct timing, and the independent source check locates their deficit near the target rather than the capable neighbour. No equality of depths is assumed. See depth-sanity-417917895.json.

R131. TIC 26804032

physical_verdict: CONFIRMED

novelty_status: uncatalogued within seven scoped catalogue checks; no exhaustive priority claim

next_check: See target report for limitations.

Archived source: sanitized report text.

TIC 26804032

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [17, 57, 84]; depths 133.48 to 143.87 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=7.220041788 d from event centres. Timing RMS=0.692 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached eclipse difference image concentrates the lost flux in the target image; target/deficit distance 3.143 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; bandpass differences, uncatalogued blends and PSF modelling limit attribution.

Independent TESScut pixel aperture extraction sector 57 confirms event depths 123.72, 122.55, 124.40, 124.85 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=7.219750852 d, difference 1.60 Gaia sigma. Closest edge-on conjunction B offset 0.05455 d versus linear full SB1 covariance error 0.03521 d; timing differences and propagation limits are retained. Observed median duration 2.85 h versus approximate central main-sequence feasibility 4.74 h; mass function 0.31145 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

Next tests for characterization: exposure-integrated eclipse modelling and stellar/RV constraints; refine dilution with resolved photometry where needed. These are follow-up opportunities rather than missing execution steps.

TIC 220425369

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [1, 37, 98]; depths 123.34 to 136.89 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=16.119976613 d from event centres. Timing RMS=0.335 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached eclipse difference image concentrates the lost flux in the target image; target/deficit distance 2.491 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; bandpass differences, uncatalogued blends and PSF modelling limit attribution.

Independent TESScut pixel aperture extraction sector 98 confirms event depths 121.91, 123.70, 121.93, 125.04 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=16.119216221 d, difference 0.34 Gaia sigma. Closest edge-on conjunction A offset 0.10485 d versus linear full SB1 covariance error 0.10520 d; timing differences and propagation limits are retained. Observed median duration 5.01 h versus approximate central main-sequence feasibility 5.98 h; mass function 0.05760 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

Next tests for characterization: exposure-integrated eclipse modelling and stellar/RV constraints; refine dilution with resolved photometry where needed. These are follow-up opportunities rather than missing execution steps.

R133. TIC 311918550

physical_verdict: CONFIRMED

novelty_status: uncatalogued within seven scoped catalogue checks; no exhaustive priority claim

completion: complete

next_check: See target report for limitations.

Archived source: sanitized report text.

TIC 311918550

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [19, 45, 72]; depths 143.46 to 145.73 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=14.496458839 d from event centres. Timing RMS=0.245 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached eclipse difference image concentrates the lost flux in the target image; target/deficit distance 2.038 arcsec. Flux-capable neighbours are tested by spatial position and mixed own-pixel losses, which alone are not exclusions. Centroid displacements are descriptive, without calibrated uncertainty; bandpass differences, uncatalogued blends and PSF modelling limit attribution. High PSF fractional residual (0.774) limits the scaled-image model; attribution instead uses localized eclipse deficit and the capable-neighbour comparison.

Capable neighbour Gaia DR3 3444062260949757696: catalog separation 43.12 arcsec, required loss 29.61%, own-pixel loss 0.19%, deficit distance 42.10 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Independent TESScut pixel aperture extraction sector 45 confirms event depths 77.80, 74.00 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=14.485044215 d, difference 8.56 Gaia sigma. Closest edge-on conjunction A offset -0.27216 d versus linear full SB1 covariance error 0.52818 d; timing differences and propagation limits are retained. Observed median duration 5.01 h versus approximate central main-sequence feasibility 10.18 h; mass function 0.24285 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

Gaia orbit caveat: the eclipse-derived period differs from Gaia by 0.011414624 d (8.56 quoted Gaia period errors). Consecutive events within sectors 19,45,72 independently give 14.496321191, 14.496937924, 14.496499794 d, so the discrepancy is not caused only by long-baseline cycle assignments. Accumulated drift is about 1.15 d across 101 cycles. Gaia conjunction at the representative epoch is nevertheless compatible within its 0.528 d propagated covariance scale and the duration is geometrically feasible. The target EB is confirmed from localized repeated eclipses and the independent extraction; precise Gaia orbit agreement and orbit association are unresolved, not asserted. Next test: obtain or refit RVs to test the Gaia period against the eclipse period, and check for orbit complexity.

R134. TIC 233269866

physical_verdict: CONFIRMED

novelty_status: uncatalogued within seven scoped catalogue checks; no exhaustive priority claim

completion: complete

next_check: See target report for limitations.

Archived source: sanitized report text.

TIC 233269866

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [14, 75, 83]; depths 128.28 to 146.45 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=3.498417961 d from event centres. Timing RMS=2.013 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached eclipse difference image concentrates the lost flux in the target image; target/deficit distance 3.042 arcsec. Flux-capable neighbours are tested by spatial position and mixed own-pixel losses, which alone are not exclusions. Centroid displacements are descriptive, without calibrated uncertainty; bandpass differences, uncatalogued blends and PSF modelling limit attribution. Lead inspected the cached three-panel image. Eight-event bounded repeatability test: four-event half-stack deficit distances 3.10/3.14 arcsec from target versus 6.69/7.21 arcsec from the 9.73 arcsec neighbour. All individual deficits remain closer to target. Shifted empirical image residual is 0.145 at target versus 0.401 at neighbour. The blended template is a diagnostic, not a calibrated likelihood; repeated spatial evidence supports target attribution.

Capable neighbour Gaia DR3 2233814071198998784: catalog separation 9.73 arcsec, required loss 69.40%, own-pixel loss 10.79%, deficit distance 6.91 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Independent TESScut pixel aperture extraction sector 55 confirms event depths 97.56, 93.63, 96.58, 92.96, 97.12, 99.48, 100.76, 97.73 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=3.498430126 d, difference -0.11 Gaia sigma. Closest edge-on conjunction A offset -0.06014 d versus linear full SB1 covariance error 0.04495 d; timing differences and propagation limits are retained. Observed median duration 3.07 h versus approximate central main-sequence feasibility 4.31 h; mass function 0.06237 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

Next tests for characterization: exposure-integrated eclipse modelling and stellar/RV constraints; refine dilution with resolved photometry where needed. These are follow-up opportunities rather than missing execution steps.

Archived source: sanitized report text.

TIC 42318308

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 6 representative events in sectors [14, 53, 81]; depths 137.95 to 151.98 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=2.852761729 d from event centres. Timing RMS=2.667 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached eclipse difference image concentrates the lost flux in the target image; target/deficit distance 4.268 arcsec. Flux-capable neighbours are tested by spatial position and mixed own-pixel losses, which alone are not exclusions. Centroid displacements are descriptive, without calibrated uncertainty; bandpass differences, uncatalogued blends and PSF modelling limit attribution. High PSF fractional residual (0.523) limits the scaled-image model; attribution instead uses localized eclipse deficit and the capable-neighbour comparison.

Capable neighbour Gaia DR3 2043690510556208128: catalog separation 16.59 arcsec, required loss 49.67%, own-pixel loss 8.49%, deficit distance 14.09 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Capable neighbour Gaia DR3 2043690544915953664: catalog separation 25.25 arcsec, required loss 82.77%, own-pixel loss 7.96%, deficit distance 29.96 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Independent TESScut pixel aperture extraction sector 40 confirms event depths 70.80, 76.06, 76.34, 73.03, 76.34, 75.15, 75.91, 72.24 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=2.852714047 d, difference 0.53 Gaia sigma. Closest edge-on conjunction A offset 0.01581 d versus linear full SB1 covariance error 0.05025 d; timing differences and propagation limits are retained. Observed median duration 2.96 h versus approximate central main-sequence feasibility 4.19 h; mass function 0.08975 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

Next tests for characterization: exposure-integrated eclipse modelling and stellar/RV constraints; refine dilution with resolved photometry where needed. These are follow-up opportunities rather than missing execution steps.

TIC 101779765

PLAUSIBLE. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [13, 67, 104]; depths 115.86 to 169.48 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=3.587659343 d from event centres. Timing RMS=2.293 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached eclipse difference image concentrates the lost flux in the target image; target/deficit distance 4.166 arcsec. Flux-capable neighbours are tested by spatial position and mixed own-pixel losses, which alone are not exclusions. Centroid displacements are descriptive, without calibrated uncertainty; bandpass differences, uncatalogued blends and PSF modelling limit attribution. Lead inspected the cached three-panel image. The 3.63 arcsec neighbour lies in the same unresolved TESS image and could reproduce the loss with a 66.95% eclipse. Despite the deficit being nearer the target, these cached diagnostics do not securely distinguish the two sources; retain PLAUSIBLE pending finer spatial evidence.

Capable neighbour Gaia DR3 6666037702955206528: catalog separation 3.63 arcsec, required loss 66.95%, own-pixel loss 12.19%, deficit distance 7.85 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Independent TESScut pixel aperture extraction sector 27 confirms event depths 114.03, 112.12, 115.18, 112.35, 114.42, 110.44 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=3.587826860 d, difference -1.86 Gaia sigma. Closest edge-on conjunction A offset -0.06076 d versus linear full SB1 covariance error 0.03521 d; timing differences and propagation limits are retained. Observed median duration 3.61 h versus approximate central main-sequence feasibility 4.56 h; mass function 0.06656 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Evidence: raw-evidence/raw-events.json, raw-evidence/qlp-manifest.json, source-review.json, gaia-geometry.json, catalogue-review.json, and provenance hashes. Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

Next test: resolved eclipse-time imaging or a calibrated multi-source pixel model that can distinguish the 3.63 arcsec pair. Complete execution of the five checks does not remove source ambiguity.

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 4 representative events in sectors [36, 89]; depths 142.58 to 142.87 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=9.403393839 d from event centres. Timing RMS=0.164 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached eclipse difference image concentrates the lost flux in the target image; target/deficit distance 3.278 arcsec. No Gaia G-band flux-capable neighbour within the cached 60 arcsec search. Centroid displacements are descriptive, without calibrated uncertainty; bandpass differences, uncatalogued blends and PSF modelling limit attribution.

Independent TESScut pixel aperture extraction sector 9 confirms event depths 136.55, 135.84, 135.08 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=9.403146787 d, difference 0.60 Gaia sigma. Closest edge-on conjunction A offset 0.07789 d versus linear full SB1 covariance error 0.06159 d; timing differences and propagation limits are retained. Observed median duration 9.50 h versus approximate central main-sequence feasibility 9.94 h; mass function 0.09103 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec. Scope and alternate-identity limitations apply. Archived source: sanitized report text.

TIC 122024194

CONFIRMED. Execution: complete. Scoped novelty: no identified prior EB.

Raw QLP SAP_FLUX with QUALITY=0 yields 5 representative events in sectors [8, 36, 89]; depths 143.83 to 151.24 ppt. Quadratic local baseline plus trapezoid, native cadence, derives P=9.521588306 d from event centres. Timing RMS=0.584 min; unweighted and conditional on the search cycle counts, without a fitted uncertainty. For two-event solutions, near-zero RMS is algebraic and is not a precision claim. The helper and lead inspected the representative raw event panel and reviewed the deciding measurements; sector-dependent aperture dilution and baseline changes remain in the depths.

Cached eclipse difference image concentrates the lost flux in the target image; target/deficit distance 0.887 arcsec. Flux-capable neighbours are tested by spatial position and mixed own-pixel losses, which alone are not exclusions. Centroid displacements are descriptive, without calibrated uncertainty; bandpass differences, uncatalogued blends and PSF modelling limit attribution. High PSF fractional residual (0.998) limits the scaled-image model; attribution instead uses localized eclipse deficit and the capable-neighbour comparison. Lead inspected the three-panel image: bright off-target star dominates total light but the eclipse deficit remains at the target, 59.34 arcsec from the only flux-capable catalogued neighbour.

Capable neighbour Gaia DR3 5316688342982264064: catalog separation 58.77 arcsec, required loss 62.83%, own-pixel loss 0.18%, deficit distance 59.34 arcsec. Pixel losses include mixed source flux and are supporting spatial diagnostics.

Independent TESScut pixel aperture extraction sector 62 confirms event depths 116.05, 115.79, 116.18 ppt. Independent 3x3 target aperture with per-cadence faint-pixel background; core medians versus local pre/post baseline, without formal errors or dilution correction. This uses the same TESS images through an independent extraction pipeline, not an independent observation. Gaia coordinates projected through the cutout WCS verify the target position and header sector. Input paths/URIs and SHA256 are preserved in raw-evidence/independent-results.json.

Gaia SB1 P=9.521738143 d, difference -0.21 Gaia sigma. Closest edge-on conjunction A offset 0.00764 d versus linear full SB1 covariance error 0.12863 d; timing differences and propagation limits are retained. Observed median duration 6.79 h versus approximate central main-sequence feasibility 8.63 h; mass function 0.07780 solar masses. This is a geometry feasibility check, not a fitted stellar solution or measured inclination. Linear propagation can be approximate for nearly circular orbits.

Seven-scope central catalogue matrix marks coverage complete and no identified prior EB for this target. SIMBAD SB* alone is not an EB type; Kostov table2 is unvetted. Historical five-arcsecond batteries retain condensed rather than raw per-query receipts; VSX/ASAS-SN cones are 60 arcsec.

Scope and alternate-identity limitations apply. See catalogue-review.json and ../shared-catalogues/README.md for exact coverage.

Contributor note: an automated photometry helper measured representative raw events and checked independent reductions; the lead reviewed the deciding evidence.

Next tests for characterization: exposure-integrated eclipse modelling and stellar/RV constraints; refine dilution with resolved photometry where needed. These are follow-up opportunities rather than missing execution steps.

R141. TIC 289404005

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 289404005: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector34 custom TESScut extraction yields 2 fitted repeated eclipses, depths 364.57–364.77ppt and median duration 9.67h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 2 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 12.12231937d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing agrees within0.00020d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations.
3. Source: lead inspected the regenerated three-panel difference image. Sector34 stacks 2 eclipses; deficit centroid is 5.47arcsec from the target. The deficit follows the target PSF. No Gaia source in the cached60arcsec cone is bright enough to supply the observed dip under a total-eclipse G-flux bound. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0034/0000/0002/8940/4005/hlsp_qlp_tess_ffi_s0034-0000000289404005_tess_v01_llc.fits`, SHA256 `651f542edc8484cd673753339c77f135a1bca178a73ba16ceeedc8e22724f3af`; TIC header `289404005`, sector header `34`. Original cutout `C:\Home\sky\data\sb1-scale-c3\vet289404005\tesscut_s034.fits`, SHA256 `ab7f30f4717184862a3de31da6e809644bd6474df2033ac1d90e8f2dc0f72e69`.
5. Gaia geometry: exact DR3 source5734220496273016960, SB2, P=12.12247087 +/-0.00044127d, e=0.33954, omega=309.441deg. Closest nominal edge-on conjunctionA has observed-minus-Gaia -0.0011d (-0.00009phase). Descriptive diagonal linear uncertainty 0.0930d omits correlations and is not a selection threshold. Median duration 9.67h is below approximate central-crossing 12.41h from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

R142. TIC 335001355

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 335001355: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector11 custom TESScut extraction yields 2 fitted repeated eclipses, depths 183.21–185.17ppt and median duration 8.90h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 2 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 13.04834796d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing agrees within0.00020d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations. The target lies close to a pixel corner; an adjacent brightest deficit pixel is expected from the sampled PSF. The deficit centroid remains within0.19pixel of the target, and disappearing light is localized at its PSF rather than a capable neighbour.
3. Source: lead inspected the regenerated three-panel difference image. Sector11 stacks 2 eclipses; deficit centroid is 2.01arcsec from the target. The deficit follows the target PSF. No Gaia source in the cached60arcsec cone is bright enough to supply the observed dip under a total-eclipse G-flux bound. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0011/0000/0003/3500/1355/hlsp_qlp_tess_ffi_s0011-0000000335001355_tess_v01_llc.fits`, SHA256 `a42bf93026cf85e6854d7a5b4d8e064e98269bba39f2bdd0118494ea2c00be48`; TIC header `335001355`, sector header `11`. Original cutout `C:\Home\sky\data\sb1-scale-c3\vet335001355\tesscut_s011.fits`, SHA256 `dad2d16a719e1f5156b10eeaef29ff2930a2c96c98ae4e7df26c2f7f454d502f`.
5. Gaia geometry: exact DR3 source5844554632716451584, SB2, P=13.04463548 +/-0.000953344d, e=0.15922, omega=28.267deg. Closest nominal edge-on conjunctionA has observed-minus-Gaia +0.3490d (+0.02675phase). Descriptive diagonal linear uncertainty 0.1557d omits correlations and is not a selection threshold. Median duration 8.90h is below approximate central-crossing 12.32h

from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model. Gaia association tension is retained: photometric period versus Gaia is +3.89 quoted Gaia period errors, without a photometric period uncertainty. The observed-epoch conjunction offset is +0.3490d; propagating this same-sector period toward Gaia epoch BTJD389 gives a descriptive offset +0.0026d. This is not a precision backward ephemeris or an arbitrary sigma rejection. The near-matching orbit scale, eclipse shape and on-target localization support the binary association; joint RV/eclipse refitting remains needed.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

R143. TIC 21335382

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 21335382: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector57 custom TESScut extraction yields 2 fitted repeated eclipses, depths 486.89–491.99ppt and median duration 9.05h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 2 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 12.45151760d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing agrees within0.00020d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations.
3. Source: lead inspected the regenerated three-panel difference image. Sector57 stacks 2 eclipses; deficit centroid is 6.53arcsec from the target. The deficit follows the target PSF. No Gaia source in the cached60arcsec cone is bright enough to supply the observed dip under a total-eclipse G-flux bound. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0057/0000/0000/2133/5382/hlsp_qlp_tess_ffi_s0057-0000000021335382_tess_v01_llc.fits`, SHA256 `5b5a199436e0dc2cf5a0a63b88aa1fa3ea843f247d5189fa41b2c43c758b9b2d`; TIC header `21335382`, sector header `57`. Original cutout `C:\Home\sky\data\sb1-scale-c3\vet21335382\tesscut_s057.fits`, SHA256 `fdf6bd8cbb7e78d340edc2f46a730aabb2931b40eab1a90d6e9719f83e85efb9`.
5. Gaia geometry: exact DR3 source1912070859806006912, SB2, P=12.45160454 +/-0.000578453d, e=0.46213, omega=76.833deg. Closest nominal edge-on conjunctionB has observed-minus-Gaia +0.1459d (+0.01172phase). Descriptive diagonal linear uncertainty 0.1312d omits correlations and is not a selection threshold. Median duration 9.05h is below approximate central-crossing 12.86h from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

TIC 119830214: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector56 custom TESScut extraction yields 3 fitted repeated eclipses, depths 177.18–178.21ppt and median duration 3.37h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 3 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 11.63511433d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing agrees within0.00020d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations.
3. Source: lead inspected the regenerated three-panel difference image. Sector56 stacks 3 eclipses; deficit centroid is 2.16arcsec from the target. The deficit follows the target PSF. No Gaia source in the cached60arcsec cone is bright enough to supply the observed dip under a total-eclipse G-flux bound. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0056/0000/0001/1983/0214/hlsp_qlp_tess_ffi_s0056-0000000119830214_tess_v01_llc.fits`, SHA256 `4be53d64e17170d3d5dee57c9b0ce75b8d9bca4bd833656ba35509c291a4798f`; TIC header `119830214`, sector header `56`. Original cutout `C:\Home\sky\data\sb1-scale-c3\vet119830214\tesscut_s056.fits`, SHA256 `b9afc03835c6ff66b1355a7e61443575e50b77f565d34bb77761fb90fb37efe8`.
5. Gaia geometry: exact DR3 source1955599563080439296, SB2, P=11.63425164 +/-0.000250142d, e=0.39558, omega=100.724deg. Closest nominal edge-on conjunctionA has observed-minus-Gaia +0.2084d (+0.01791phase). Descriptive diagonal linear uncertainty 0.0581d omits correlations and is not a selection threshold. Median duration 3.37h is below approximate central-crossing 5.41h from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model. Gaia association tension is retained: photometric period versus Gaia is +3.45 quoted Gaia period errors, without a photometric

period uncertainty. The observed-epoch conjunction offset is +0.2084d; propagating this same-sector period toward Gaia epoch BTJD389 gives a descriptive offset +0.0276d. This is not a precision backward ephemeris or an arbitrary sigma rejection. The near-matching orbit scale, eclipse shape and on-target localization support the binary association; joint RV/eclipse refitting remains needed.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

R145. TIC 170081245

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 170081245: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector7 custom TESScut extraction yields 4 fitted repeated eclipses, depths 391.43–489.49ppt and median duration 5.34h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 4 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 13.14022437d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing agrees within0.00020d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations. The 6.57011219 d spacing alternates two distinct eclipse depths (QLP about405/505 ppt), so it is half the orbital period. The full eclipse orbital period is13.14022437 d, compared with Gaia13.14065290 d; the enormous naive half-period sigma discrepancy is not a physical disagreement. Both eclipse families lie at the two conjunctions. The target lies close to a pixel corner; an adjacent brightest deficit pixel is expected from the sampled PSF. The deficit centroid remains within0.19pixel of the target, and disappearing light is localized at its PSF rather than a capable neighbour.
3. Source: lead inspected the regenerated three-panel difference image. Sector7 stacks 4 eclipses; deficit centroid is 3.18arcsec from the target. The deficit follows the target PSF. No Gaia source in the cached60arcsec cone is bright enough to supply the observed dip under a total-eclipse G-flux bound. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 309600815: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector19 custom TESScut extraction yields 2 fitted repeated eclipses, depths 157.10–158.48ppt and median duration 3.91h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 2 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 18.47635049d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing agrees within0.00020d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations. The high global PSF residual0.90 includes a bright separate star near pixel(4,13). The central5x5 rerun gives residual0.093 and scale0.1487, matching1x1/3x3 depths0.1498/0.1497. See diff_fitr2.json/png.
3. Source: lead inspected the regenerated three-panel difference image. Sector19 stacks 2 eclipses; deficit centroid is 4.59arcsec from the target. The deficit follows the target PSF. No Gaia source in the cached60arcsec cone is bright enough to supply the observed dip under a total-eclipse G-flux bound. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0019/0000/0003/0960/0815/hlsp_qlp_tess_ffi_s0019-0000000309600815_tess_v01_llc.fits`, SHA256 `f2460899bc2fa427eab4c3142fdf7ce865ae4d9ce7d5874b8515e3e98161253d`; TIC header `309600815`, sector header `19`. physical_verdict: PROBABLE

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Refit the Gaia SB2 radial velocities jointly with the long-baseline eclipse ephemeris to resolve the orbital association.

Archived source: sanitized report text.

TIC 47719859: PROBABLE

Four bounded checks support a real eclipsing binary on the target; Gaia orbit association remains unresolved. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector33 custom TESScut extraction yields 2 fitted repeated eclipses, depths 195.27-197.40ppt and median duration 14.07h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 2 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 16.60121222d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing differs by 0.000245d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations.
3. Source: lead inspected the regenerated three-panel difference image. Sector33 stacks 1 eclipses; deficit centroid is 2.36arcsec from the target. The deficit follows the target PSF. No Gaia source in the cached 60 arcsec cone can supply the dip under the approximate total-eclipse G-flux bound. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0033/0000/0000/4771/9859/hlsp_qlp_tess_ffi_s0033-0000000047719859_tess_v01_llc.fits`, SHA256 `958695611c810549e89188356debca3f3bbb3cd7c1ced523cf1a17f083046a1b`; TIC header `47719859`, sector header `33`. Original cutout `C:\Home\sky\data\sb1-scale-c3\vet47719859\tesscut_s033.fits`, SHA256 `ebb00e2f7c381594bdbaa7dc212f8a00c4243ccd51173316ab7c8d1065e079c3`.
5. Gaia geometry: exact DR3 source2924835486919571456, SB2, P=16.60764684 +/-0.000773742d, e=0.07987, omega=13.721deg. Closest nominal edge-on conjunctionA has observed-minus-Gaia -0.3802d (-0.02289phase). Descriptive diagonal linear uncertainty 0.1942d omits correlations and is not a selection threshold. Median duration 14.07h is below approximate central-crossing 17.37h from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model. Association tension is retained: same-sector photometric period minus Gaia is -0.006435d (-8.32 quoted Gaia-error units, without a

photometric uncertainty). The observed conjunction difference is -0.3802d. No arbitrary sigma veto is used; timing precision, propagation covariance and joint RV/eclipse refitting are open limitations. The duration, approximately matching orbital scale and on-target eclipses support an association, subject to the explicit case assessment below. Additional independent helper timing of QLP sector6 (BTJD1479.79932) and sector87 (BTJD3671.20781 and3687.81117) establishes a roughly16.60157d long-baseline period. Gaia16.60765d accumulates about0.8d drift over132cycles. This is physical timing tension across years, rather than a formal-error cutoff. The Gaia association/geometry check remains unresolved, giving PROBABLE. See ../../helper/HELPER-AUDIT.md and numerical evidence.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Refit the Gaia SB2 radial velocities jointly with the long-baseline eclipse ephemeris to resolve the orbital association.

R154. TIC 350335402

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 350335402: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector63 custom TESScut extraction yields 4 fitted repeated eclipses, depths 25.53-29.10ppt and median duration 4.76h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 4 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 6.07475422d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing differs by 0.000225d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations.
3. Source: lead inspected the regenerated three-panel difference image. Sector63 stacks 3 eclipses; deficit centroid is 2.43arcsec from the target. The deficit follows the target PSF. The capable G=8.90 star at26.19arcsec dominates blended light but the disappearing light is centered on the target, approximately28.7arcsec from that neighbour. The high global single-PSF residual0.82 reflects the blend; the deficit map separates the eclipsing target from the brighter neighbour. The G=13.49 neighbour is also spatially displaced. The custom 3x3 aperture is strongly diluted (about26ppt versus QLP about180ppt), yet reproduces timing and shape. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0063/0000/0003/5033/5402/hlsp_qlp_tess_ffi_s0063-0000000350335402_tess_v01_llc.fits`, SHA256 `2327b89618800f96dfc7e3257c6c0cbdb3e70f80f7e923d2b4d1cdd93ef6b296`; TIC header `350335402`, sector header `63`. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

R156. TIC 382260140

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 382260140: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector97 custom TESScut extraction yields 9 fitted repeated eclipses, depths 172.93-174.53ppt and median duration 4.07h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 6 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 5.70086500d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing differs by 0.000016d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations.
3. Source: lead inspected the regenerated three-panel difference image. Sector97 stacks 9 eclipses; deficit centroid is 2.23arcsec from the target. The deficit follows the target PSF. The capable G=12.23 neighbour59.55arcsec away is far from the compact on-target deficit; it would require about69% loss in the approximate G-flux test. The deficit centroid is2.23arcsec from the target. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0097/0000/0003/8226/0140/hlsp_qlp_tess_ffi_s0097-0000000382260140_tess_v01_llc.fits`, SHA256 `0e4734661c5c232201dfc466c2d9c5bd2dee1144189047c98b9f43e0a1c3629f`; TIC header `382260140`, sector header `97`. Original cutout `C:\Home\sky\data\sb1-scale-c3\vet382260140\tesscut_s097.fits`, SHA256 `f154d7cc8b80bf628c69bc5db623a535b1caaf77c3b4d085be92e3010e0b01a5`.
5. Gaia geometry: exact DR3 source4760187364544951296, SB1, P=5.70012067 +/-0.000378308d, e=0.35298, omega=62.608deg. Closest nominal edge-on conjunctionA has observed-minus-Gaia +0.4246d (+0.07449phase). Descriptive diagonal linear uncertainty 0.2407d omits correlations and is not a selection threshold. Median duration 4.07h is below approximate central-crossing 4.88h from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model. Association tension is retained:

same-sector photometric period minus Gaia is +0.000744d (+1.97 quoted Gaia-error units, without a photometric uncertainty). The observed conjunction difference is +0.4246d. No arbitrary sigma veto is used; timing precision, propagation covariance and joint RV/eclipse refitting are open limitations. The duration, approximately matching orbital scale and on-target eclipses support an association, subject to the explicit case assessment below.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

R158. TIC 358766055

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 358766055: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector22 custom TESScut extraction yields 5 fitted repeated eclipses, depths 135.35-136.93ppt and median duration 4.74h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 4 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 4.69530532d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing differs by 0.000006d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations.
3. Source: lead inspected the regenerated three-panel difference image. Sector22 stacks 5 eclipses; deficit centroid is 0.81arcsec from the target. The deficit follows the target PSF. A capable G=12.15 neighbour is only11.15arcsec (0.53pixel) away, so spatial resolution is limited. The deficit centroid is0.81arcsec from the target and about11arcsec from that neighbour; the loss peak and fractional-loss gradient favor the target. A second capable source53.25arcsec away is not at the deficit. Subpixel attribution has no calibrated uncertainty, and unresolved-source alternatives remain limited by the TESS PSF. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0022/0000/0003/5876/6055/hlsp_qlp_tess_ffi_s0022-0000000358766055_tess_v01_llc.fits`, SHA256 `4cc80b8df8ba4cb07510949831b85fd3af182a3c5a1325648a5a3945f07d14ff`; TIC header `358766055`, sector header `22`. 5. Gaia geometry: exact DR3 source4035203795583052928, SB1, P=4.69568965 +/-0.0003026d, e=0.02993, omega=34.932deg. Closest nominal edge-on conjunctionA has observed-minus-Gaia -0.0580d (-0.01234phase). Descriptive diagonal linear uncertainty 0.9157d omits correlations and is

not a selection threshold. Median duration 4.74h is below approximate central-crossing 5.17h from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

R159. TIC 37307440

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 37307440: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector98 custom TESScut extraction yields 6 fitted repeated eclipses, depths 284.41-289.37ppt and median duration 4.19h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 3 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 8.08017268d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing differs by 0.000086d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations.
3. Source: lead inspected the regenerated three-panel difference image. Sector98 stacks 6 eclipses; deficit centroid is 5.77arcsec from the target. The deficit follows the target PSF. The capable G=12.08 neighbour28.996arcsec away would require about96% eclipse in the approximate G-flux test, and lies about30arcsec from the disappearing-light centroid. The deficit peaks at the target. Its centroid is5.77arcsec from the target; the asymmetry is much smaller than the target-neighbour separation. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. 5. Gaia geometry: exact DR3 source6721529195837003136, SB1, P=5.64491860 +/-0.000249817d, e=0.01848, omega=72.053deg. Closest nominal edge-on conjunctionA has observed-minus-Gaia -0.0798d (-0.01414phase). Descriptive diagonal linear uncertainty 0.7875d omits correlations and is not a selection threshold. Median duration 4.88h is below approximate central-crossing 6.50h from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

R161. TIC 266486943

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Joint RV/eclipse modeling and longer-baseline eclipse timing; resolve remaining alias and geometry uncertainty.

Archived source: sanitized report text.

TIC 266486943: CONFIRMED

All five bounded checks were attempted and adjudicated. Execution is complete; physical verdict and catalogue novelty are separate.

1. Representative raw repeat: custom TESScut sector14 gives3 fitted eclipses; independently downloaded raw QLP SAP_FLUX QUALITY=0 gives3. The lead inspected two individual raw SAP eclipse panels. Sharp ingress/egress and repeat dips persist without relying on a folded curve. Local quadratic baseline plus trapezoid event times, depths and durations appear in ../../raw-evidence/raw-events.json and qlp-results.json.
2. Eclipse timing: representative orbital/recurrence period9.21918551d, QLP9.21919404d, conditional on seed cycle counts. Same-sector data provide no formal photometric period uncertainty; two-event cases verify recurrence with limited alias precision.
3. Attribution: sector14 difference image stacks3 events; target-to-deficit centroid6.74arcsec, without calibrated uncertainty. The lead inspected all three panels. No brightness-capable neighbour is present in the cached60arcsec cone under a total-eclipse G-flux bound. Global PSF residual0.221 is descriptive and includes field light. Approximate G-band brightness bounds do not address missing/unresolved sources or all colour/throughput differences.
4. Reduction robustness: separately coded3x3 TESScut extraction and QLP SAP reproduce individual events; these share the same TESS FFI photons, not independent observations. QLP URI `mast:HLSP/qlp/s0014/0000/0002/6648/6943/hlsp_qlp_tess_ffi_s0014-0000000266486943_tess_v01_llc.fits`, TIC header266486943, sector14, SHA256 `2f843bca81f34d2cc2fcee58426b39659057a5696bb57794696f45fa0f3274a6`. TESScut source `C:\Home\sky\data\sb1-scale-c3\vet266486943\tesscut_s014.fits`, SHA256 `9e1a52c351e44ee50a3ea25e20ddd65271e606303d5938e3b87286d5857520e1`. Seed and Gaia-cone provenance hashes are in raw-events.json.
5. Gaia geometry: exact DR3213789185645608912, SB1, P=9.21858901 +/-0.000618254d, e=0.33310, omega=152.801deg. Nominal edge-on conjunctionA has observed-minus-predicted offset+0.1356d (+0.01470phase). Descriptive diagonal linear uncertainty is0.1040d; it omits parameter covariance and is no sigma veto. Observed median duration4.84h versus approximate central-crossing5.76h permits a shorter chord. Duration estimate uses TIC radius and minimum-mass/main-sequence dimensions and is not a unique fitted geometry. Full NSS rows including covariance fields are preserved in the shared catalogue file. Geometry is compatible at this bounded feasibility level, with orbital precision retained as a limitation.

Catalogue status: no identified prior EB; coverage complete=yes. Prior identification: []. Central seven-scope receipts and Chopard fields are in ../../../shared-catalogues/coverage-matrix.csv. Known recoveries are excluded from new discoveries. No exhaustive publication-priority claim.

Limits: representative selected-sector events, native cadence without exposure integration, no precision stellar solution, cached Gaia cone and unresolved-source limitations. No contrary artifact is established by these limitations.

Next check: Joint RV/eclipse modeling and longer-baseline eclipse timing; resolve remaining alias and geometry uncertainty.

R162. TIC 129280729

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Joint RV/eclipse modeling and longer-baseline eclipse timing; resolve remaining alias and geometry uncertainty.

Archived source: sanitized report text.

TIC 129280729: CONFIRMED

All five bounded checks were attempted and adjudicated. Execution is complete; physical verdict and catalogue novelty are separate.

1. Representative raw repeat: custom TESScut sector67 gives2 fitted eclipses; independently downloaded raw QLP SAP_FLUX QUALITY=0 gives2. The lead inspected two individual raw SAP eclipse panels. Sharp ingress/egress and repeat dips persist without relying on a folded curve. Local quadratic baseline plus trapezoid event times, depths and durations appear in ../../raw-evidence/raw-events.json and qlp-results.json.
2. Eclipse timing: representative orbital/recurrence period13.97841193d, QLP13.97836065d, conditional on seed cycle counts. Same-sector data provide no formal photometric period uncertainty; two-event cases verify recurrence with limited alias precision.
3. Attribution: sector67 difference image stacks2 events; target-to-deficit centroid2.08arcsec, without calibrated uncertainty. The lead inspected all three panels. No brightness-capable neighbour is present in the cached60arcsec cone under a total-eclipse G-flux bound. Global PSF residual0.078 is descriptive and includes field light. Approximate G-band brightness bounds do not address missing/unresolved sources or all colour/throughput differences.
4. Reduction robustness: separately coded3x3 TESScut extraction and QLP SAP reproduce individual events; these share the same TESS FFI photons, not independent observations. QLP URI `mast:HLSP/qlp/s0067/0000/0001/2928/0729/hlsp_qlp_tess_ffi_s0067-0000000129280729_tess_v01_llc.fits`, TIC header129280729, sector67, SHA256 `22e806269a245dba47fb0590bc62220092b41b9ab3e9565bd2b4c9b641f4540a`. Nominal edge-on conjunctionA has observed-minus-predicted offset-0.1453d (-0.01039phase). Descriptive diagonal linear uncertainty is0.5932d; it omits parameter covariance and is no sigma veto. Observed median duration8.99h versus approximate central-crossing10.91h permits a shorter chord. Duration estimate uses TIC radius and minimum-mass/main-sequence dimensions and is not a unique fitted geometry. Full NSS rows including covariance fields are preserved in the shared catalogue file. Geometry is compatible at this bounded feasibility level, with orbital precision retained as a limitation.

Catalogue status: no identified prior EB; coverage complete=yes. Prior identification: []. Central seven-scope receipts and Chopard fields are in ../../../shared-catalogues/coverage-matrix.csv. Known recoveries are excluded from new discoveries. No exhaustive publication-priority claim.

Limits: representative selected-sector events, native cadence without exposure integration, no precision stellar solution, cached Gaia cone and unresolved-source limitations. No contrary artifact is established by these limitations.

Next check: Joint RV/eclipse modeling and longer-baseline eclipse timing; resolve remaining alias and geometry uncertainty.

R163. TIC 407991939

physical_verdict: CONFIRMED

novelty_status: known catalogue EB recovery; excluded from additions

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Joint RV/eclipse modeling and longer-baseline eclipse timing; resolve remaining alias and geometry uncertainty.

Archived source: sanitized report text.

TIC 407991939: CONFIRMED

All five bounded checks were attempted and adjudicated. Execution is complete; physical verdict and catalogue novelty are separate.

1. Representative raw repeat: custom TESScut sector32 gives16 fitted eclipses; independently downloaded raw QLP SAP_FLUX QUALITY=0 gives16. The lead inspected two individual raw SAP eclipse panels. Sharp ingress/egress and repeat dips persist without relying on a folded curve. Local quadratic baseline plus trapezoid event times, depths and durations appear in ../../raw-evidence/raw-events.json and qlp-results.json.
2. Eclipse timing: representative orbital/recurrence period1.44652348d, QLP1.44651023d, conditional on seed cycle counts. Same-sector data provide no formal photometric period uncertainty; two-event cases verify recurrence with limited alias precision. The external ASAS-SN prior EB record lists2.8932d, twice the observed1.44652d spacing. Odd/even QLP depths are nearly equal, without a secure alternating family; both2.89301230/2.89302959d family fits are tabulated in alias-check.json. The representative eclipse recurrence agrees with Gaia1.44654138d. The external double-period alternative remains a characterization ambiguity requiring joint RV/eclipse modeling; the on-target repeating binary interpretation is secure.
3. Attribution: sector32 difference image stacks16 events; target-to-deficit centroid3.62arcsec, without calibrated uncertainty. The lead inspected all three panels. No brightness-capable neighbour is present in the cached60arcsec cone under a total-eclipse G-flux bound. Global PSF residual0.181 is descriptive and includes field light. Approximate G-band brightness bounds do not address missing/unresolved sources or all colour/throughput differences.
4. Reduction robustness: separately coded3x3 TESScut extraction and QLP SAP reproduce individual events; these share the same TESS FFI photons, not independent observations. QLP URI `mast:HLSP/qlp/s0032/0000/0004/0799/1939/hlsp_qlp_tess_ffi_s0032-0000000407991939_tess_v01_llc.fits`, TIC header407991939, sector32, SHA256 `7ae5db8f54248ba784e9621395fca3ace7d6da54f8535e47208b457be801fee3`. TESScut source `C:\Home\sky\data\sb1-scale-c3\vet407991939\tesscut_s032.fits`, SHA256 `21489df6407eb6b27f5df92c143efc8fccc28881081ba07345d383f2a553d976`. Seed and Gaia-cone provenance hashes are in raw-events.json.
5. Gaia geometry: exact DR33297974617731416192, SB1, P=1.44654138 +/-2.59957e-05d, e=0.03896, omega=81.869deg. Nominal edge-on conjunctionA has observed-minus-predicted offset-0.0279d (-0.01928phase). Descriptive diagonal linear uncertainty is0.1924d; it omits parameter covariance and is no sigma veto. Observed median duration2.62h versus approximate central-crossing2.89h permits a shorter chord. Duration estimate uses TIC radius and minimum-mass/main-sequence

dimensions and is not a unique fitted geometry. Full NSS rows including covariance fields are preserved in the shared catalogue file. Geometry is compatible at this bounded feasibility level, with orbital precision retained as a limitation.

physical_verdict: CONFIRMED

novelty_status: known catalogue EB recovery; excluded from additions

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Higher-resolution eclipse photometry or calibrated PRF fitting to resolve the close capable neighbour; joint RV/eclipse timing fit.

Archived source: sanitized report text.

TIC 407220461: CONFIRMED

All five bounded checks were attempted and adjudicated. Execution is complete; physical verdict and catalogue novelty are separate.

1. Representative raw repeat: custom TESScut sector65 gives7 fitted eclipses; independently downloaded raw QLP SAP_FLUX QUALITY=0 gives7. The lead inspected two individual raw SAP eclipse panels. Sharp ingress/egress and repeat dips persist without relying on a folded curve. Local quadratic baseline plus trapezoid event times, depths and durations appear in ../../raw-evidence/raw-events.json and qlp-results.json.
2. Eclipse timing: representative orbital/recurrence period8.71639950d, QLP8.71650574d, conditional on seed cycle counts. Same-sector data provide no formal photometric period uncertainty; two-event cases verify recurrence with limited alias precision. Two eclipse families recur: QLP even-cycle depths194.46–196.44ppt versus odd191.09–191.92ppt, with different durations. The full orbital period uses the three even-family events; the other family yields custom8.71608068d and QLP8.71620836d. The final partial event cycle336 has depth55ppt and is excluded from family timing. A single-spacing fit mixed both families and is not the orbital period. Gaia SB2 supports the full period.
3. Attribution: sector65 difference image stacks7 events; target-to-deficit centroid3.16arcsec, without calibrated uncertainty. The lead inspected all three panels. A capable Gaia neighbour at19.71arcsec, G=11.997, needs intrinsic fractional eclipse0.389. Its pixel location is[8.462017061800161, 8.476938922250216]; target[7.533516138926501, 7.9955342627381825], deficit[7.606046951775297, 8.127308327133484]. The lead inspected the image: disappearing light is centered on the target PSF, not the neighbour. Its rounded-pixel fractional loss0.1282 must not be interpreted as source-separated photometry. This neighbour is only1.04pixels from the target; target attribution is favored by the0.15pixel target-to-deficit distance versus0.90pixel neighbour-to-deficit distance, without calibrated significance or source-separated PRF fitting. The close blend remains a material limitation. Global PSF residual0.361 is descriptive and includes field light. Approximate G-band brightness bounds do not address missing/unresolved sources or all colour/throughput differences.
4. Reduction robustness: separately coded3x3 TESScut extraction and QLP SAP reproduce individual events; these share the same TESS FFI photons, not independent observations. QLP URI `mast:HLSP/qlp/s0065/0000/0004/0722/0461/hlsp_qlp_tess_ffi_s0065-0000000407220461_tess_v01_llc.fits`, TIC header407220461, sector65, SHA256 `d23a36469d021f29abe879e0c97962784fad7eeb671d446dea98aabdc054e812`. physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Joint RV/eclipse modeling and longer-baseline eclipse timing; resolve remaining alias and geometry uncertainty.

Archived source: sanitized report text.

TIC 28634340: CONFIRMED

All five bounded checks were attempted and adjudicated. Execution is complete; physical verdict and catalogue novelty are separate.

1. Representative raw repeat: custom TESScut sector14 gives2 fitted eclipses; independently downloaded raw QLP SAP_FLUX QUALITY=0 gives2. The lead inspected two individual raw SAP eclipse panels. Sharp ingress/egress and repeat dips persist without relying on a folded curve. Local quadratic baseline plus trapezoid event times, depths and durations appear in ../../raw-evidence/raw-events.json and qlp-results.json.
2. Eclipse timing: representative orbital/recurrence period14.46235876d, QLP14.46302687d, conditional on seed cycle counts. Same-sector data provide no formal photometric period uncertainty; two-event cases verify recurrence with limited alias precision.
3. Attribution: sector14 difference image stacks2 events; target-to-deficit centroid4.02arcsec, without calibrated uncertainty. The lead inspected all three panels. No brightness-capable neighbour is present in the cached60arcsec cone under a total-eclipse G-flux bound. Global PSF residual0.346 is descriptive and includes field light. Approximate G-band brightness bounds do not address missing/unresolved sources or all colour/throughput differences.
4. Reduction robustness: separately coded3x3 TESScut extraction and QLP SAP reproduce individual events; these share the same TESS FFI photons, not independent observations. QLP URI `mast:HLSP/qlp/s0014/0000/0000/2863/4340/hlsp_qlp_tess_ffi_s0014-0000000028634340_tess_v01_llc.fits`, TIC header28634340, sector14, SHA256 `dcb3a6cbf9b2f144d6e10ffb10fb0f9c070017321086216deeb0258d36265908`. TESScut source `C:\Home\sky\data\sb1-scale-c3\vet28634340\tesscut_s014.fits`, SHA256 `72da5784bd8cbdc9f94156a334055a9f3523c45389ec4d317127b34f717684bb`. Seed and Gaia-cone provenance hashes are in raw-events.json.
5. Gaia geometry: exact DR32090237648120950528, SB1, P=14.46244572 +/-0.000782566d, e=0.52544, omega=346.747deg. Nominal edge-on conjunctionA has observed-minus-predicted offset+0.2213d (+0.01530phase). Descriptive diagonal linear uncertainty is0.0945d; it omits parameter covariance and is no sigma veto. Observed median duration6.60h versus approximate central-crossing8.50h permits a shorter chord. Duration estimate uses TIC radius and minimum-mass/main-sequence dimensions and is not a unique fitted geometry. Full NSS rows including covariance fields are preserved in the shared catalogue file. Geometry is compatible at this bounded feasibility level, with orbital precision retained as a limitation.

Catalogue status: no identified prior EB; coverage complete=yes. Prior identification: []. Central seven-scope receipts and Chopard fields are in ../../../shared-catalogues/coverage-matrix.csv. Known recoveries are excluded from new discoveries. No exhaustive publication-priority claim.

Limits: representative selected-sector events, native cadence without exposure integration, no precision stellar solution, cached Gaia cone and unresolved-source limitations. No contrary artifact is established by these limitations.

Next check: Joint RV/eclipse modeling and longer-baseline eclipse timing; resolve remaining alias and geometry uncertainty.

R170. TIC 178080174

physical_verdict: CONFIRMED

Nominal edge-on conjunctionA has observed-minus-predicted offset+0.4963d (+0.04517phase). Descriptive diagonal linear uncertainty is2.8773d; it omits parameter covariance and is no sigma veto. Observed median duration4.92h versus approximate central-crossing6.04h permits a shorter chord. Duration estimate uses TIC radius and minimum-mass/main-sequence dimensions and is not a unique fitted geometry. Full NSS rows including covariance fields are

preserved in the shared catalogue file. Geometry is compatible at this bounded feasibility level, with orbital precision retained as a limitation.

Catalogue status: no identified prior EB; coverage complete=yes. Prior identification: []. Central seven-scope receipts and Chopard fields are in ../../../shared-catalogues/coverage-matrix.csv. Known recoveries are excluded from new discoveries. No exhaustive publication-priority claim.

Limits: representative selected-sector events, native cadence without exposure integration, no precision stellar solution, cached Gaia cone and unresolved-source limitations. No contrary artifact is established by these limitations.

Next check: Joint RV/eclipse modeling and longer-baseline eclipse timing; resolve remaining alias and geometry uncertainty.

R171. TIC 11661051

physical_verdict: CONFIRMED

novelty_status: uncatalogued; seven recorded catalogue scopes complete

completion: completed; five bounded checks adjudicated; limitations retained

next_check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Archived source: sanitized report text.

TIC 11661051: CONFIRMED

The five bounded original checks support a real eclipsing binary on the target. Physical verdict and catalogue novelty are separate. Full review is completed under ../../../BRIEF.md, with the limitations below.

1. Raw events: sector89 custom TESScut extraction yields 9 fitted repeated eclipses, depths 164.80-167.57ppt and median duration 3.32h. Separately downloaded raw QLP SAP_FLUX with QUALITY=0 gives 9 repeated events. Local quadratic baseline and trapezoid fits preserve the sharp eclipse structure. Measurements and individual times are in ../../raw-evidence/raw-events.json and qlp-results.json; raw scatter is in qlp-raw-event-panels.png.
2. Eclipse timing: orbital period 3.01562499d, conditional on seed cycle counts, measured from representative same-sector eclipse times. The QLP and custom extraction spacing differs by 0.000026d. No formal period error, exhaustive event count, or long-baseline precision is claimed. Two-event cases test recurrence but leave alias/precision limitations.
3. Source: lead inspected the regenerated three-panel difference image. Sector89 stacks 8 eclipses; deficit centroid is 2.10arcsec from the target. The deficit follows the target PSF. No Gaia source in the cached 60 arcsec cone can supply the dip under the approximate total-eclipse G-flux bound. The bound is approximate in TESS band; unresolved companions, missing catalogue sources and colour/throughput remain limitations. No calibrated centroid uncertainty is claimed. Pixel corner and global-fit residual diagnostics are adjudicated physically rather than used as automatic vetoes.
4. Independent reduction: QLP SAP and a separately coded3x3 TESScut aperture extraction reproduce the events. They share the same TESS FFI photons; this tests reduction robustness, not independent astrophysical observations. QLP URI `mast:HLSP/qlp/s0089/0000/0000/1166/1051/hlsp_qlp_tess_ffi_s0089-0000000011661051_tess_v01_llc.fits`, SHA256 `ef7d78689acce58fa811505c55cd77b16e8bb3e3a2249f3a8f8c79169196bc2d`; TIC header `11661051`, sector header `89`. Original cutout `C:\Home\sky\data\sb1-scale-c3\vet11661051\tesscut_s089.fits`, SHA256 `8b8743591dcb3d75dabe99e9d8a51ca5a6c2bffcd2a04c3cde13592a75901747`.
5. Gaia geometry: exact DR3 source5640517229145492480, SB1, P=3.01567156 +/-8.62197e-05d, e=0.03082, omega=241.350deg. Closest nominal edge-on conjunctionA has observed-minus-Gaia -0.0882d (-0.02924phase). Descriptive diagonal linear uncertainty 0.3315d omits correlations and is not a selection threshold. Median duration 3.32h is below approximate central-crossing 3.99h from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Alias assessment: The bounded half-phase check finds much shallower intervening flux losses (median 13.64ppt versus 174.77ppt at primary), supporting unequal flux losses at the adopted orbital period rather than equal eclipses at P/2. Window losses alone do not establish a resolved secondary-eclipse shape. The Gaia orbital period near P further supports the adopted alias. Numeric windows in ../../alias-check.json.

5. Gaia geometry: exact DR3 source1664427924600302976, SB1, P=14.32103263 +/-0.00213433d, e=0.29401, omega=167.256deg. Closest nominal edge-on conjunctionA has observed-minus-Gaia +0.0558d (+0.00390phase). Descriptive diagonal linear uncertainty 0.3743d omits correlations and is not a selection threshold. Median duration 5.85h is below approximate central-crossing 7.13h from TIC radius and minimum-mass/main-sequence companion dimensions; shorter chords are feasible. This is a feasibility check, not a fitted unique stellar model.

Catalogue status: no identified prior EB; scoped coverage complete=yes. Exact row and seven-group receipt provenance: ../../../shared-catalogues/coverage-matrix.csv and README.md. Non-eclipsing variability entries do not establish a prior EB; unvetted machine classifications remain distinct. No exhaustive publication-priority claim. Chopard exact-overlap fields are retained in the shared matrix.

Limitations: native cadence without exposure integration; local fit errors not interpreted as precision parameter errors; selected same-sector events rather than every available event; cached Gaia neighbour cone and approximate G-band feasibility; no spatial resolution below the TESS PSF. None is evidence of a contrary artifact in these data.

Next check: Fit joint RV/eclipse geometry and a longer timing baseline; retain same-sector period limitations.

Alias assessment: Only two representative primary eclipses are fitted. The same-sector spacing agrees with Gaia P=14.322d. No adequately covered half-period core survives the simple QUALITY=0 coverage test; P/2 alias is not independently excluded by that test. Recurrence plus Gaia period supports the adopted orbital period, with cycle-count and precision limitations retained. Numeric windows in ../../alias-check.json.

Spectroscopic-orbit period folds: G 11.5-12 evidence

R175. TIC 300217120

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 300217120: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 3 distinct eclipse events in selected sectors[67, 94]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=14.1585774920 ±0.0000275211d, reference primary epoch BTJD3141.0351408. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S27 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.744arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.167. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths42.769/41.065/39.999ppt, with 1 stacked events. QLP primary fitted median37.866ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3669231262924854451 2, P=14.1570493482±0.0030226820d, e=0.361127, omega=263.6297deg. Closest edge-on conjunction offset0.117178d (0.008277phase), full-SB1-covariance linear propagated Gaia uncertainty0.528972d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.179282d (photometric period projection allowance0.005339d). The approximate central duration15.03h vs observed median10.88h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: The nearby other eclipse in S67 contaminates a wider baseline window; the final fit uses a narrower 1.65-search-duration half-window and shows the repeated primary. Historical S27 TESScut contains one event but QLP independently shows three primaries in S67/S94.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt
94	155	3863.1220326	0.001157	37.866
94	156	3877.2817199	0.001157	37.629
67	104	3141.0351516	0.001157	42.190

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, raw/QLP FITS; historical/diff_s27.json, historical/diff_s27.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

R176. TIC 424716057

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 424716057: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 3 distinct eclipse events in selected sectors[12, 93, 103]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=15.4054973311 ±0.0000549956d, reference primary epoch BTJD1625.9468850. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S39 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation2.419arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.238. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths234.984/232.422/220.392ppt, with 2 stacked events. QLP primary fitted median211.907ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3582545374493105497 6, P=15.4065923405±0.0006721503d, e=0.391939, omega=272.5732deg. Closest edge-on conjunction offset0.082020d (0.005324phase), full-SB1-covariance linear propagated Gaia uncertainty0.102131d at the measured epoch. Near-Gaia-reference projected eclipse offset0.169621d (photometric period projection allowance0.004400d). The approximate central duration13.73h vs observed median11.16h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: QLP primary depths vary across apertures/sectors (205–230 ppt in the selected sectors); no common intrinsic depth is claimed.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 265350422: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[61, 99]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=8.4481707258 ±0.0000128420d, reference primary epoch BTJD2970.8043462. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S61 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.580arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.264. Capable neighbours: Gaia 577614316095585920: 32.85 arcsec, G16.170, required fractional eclipse0.566, pixel fractional loss0.0026182148905397186; Gaia 577614689757476480: 42.38 arcsec, G16.539, required fractional eclipse0.793, pixel fractional loss0.001448830988856897; Gaia 577614316096822528: 51.78 arcsec, G13.539, required fractional eclipse0.057, pixel fractional loss0.0014103835015173963
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths8.432/7.145/6.256ppt, with 3 stacked events. QLP primary fitted median7.800ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3577614689757449728, P=8.4481578354±0.0007776419d, e=0.010725, omega=80.7600deg. Closest edge-on conjunction offset-0.006714d (-0.000795phase), full-SB1-covariance linear propagated Gaia uncertainty0.249030d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.010659d (photometric period projection allowance0.003930d). The approximate central duration4.96h vs observed median1.65h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Three G-band-capable neighbours at 32.85, 42.38 and 51.78 arcsec lie away from the compact deficit on the target. The target-centered dip grows rather than vanishes in the small aperture. No calibrated centroid confidence ellipse is available.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 274941915: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[76, 83]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=10.1329390738 ±0.0000628576d, reference primary epoch BTJD3371.1764455. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S83 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation5.332arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.265. Capable neighbours: Gaia 1967100282911816960: 32.98 arcsec, G15.918, required fractional eclipse0.586, pixel fractional loss0.010377045342031255; Gaia 1967100282911812224: 40.57 arcsec, G15.999, required fractional eclipse0.630, pixel fractional loss0.00914697883875284; Gaia 1967100385991024896: 47.81 arcsec, G16.085, required fractional eclipse0.682, pixel fractional loss0.005402736181751521
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths10.256/9.725/9.397ppt, with 3 stacked events. QLP primary fitted median10.415ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR31967100282911815040, P=10.1324824053±0.0027856675d, e=0.042312, omega=29.1410deg. Closest edge-on conjunction offset0.156872d (0.015482phase), full-SB1-covariance linear propagated Gaia uncertainty0.910278d at the measured epoch. Near-Gaia-reference projected eclipse offset0.022611d (photometric period projection allowance0.018480d). The approximate central duration4.17h vs observed median1.94h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Three capable neighbours at 32.98, 40.57 and 47.81 arcsec are spatially separated from the target-centered compact deficit. The small-aperture reduction retains the eclipse. No calibrated centroid confidence ellipse is available.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry / multi-source PRF localization

Archived source: sanitized report text.

TIC 253126207: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 3 distinct eclipse events in selected sectors[11, 65]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=17.4365709217 ±0.0000882356d, reference primary epoch BTJD1604.0901103. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: unresolved after check.** Historical S11 deficit peak[0, 4] vs target pixel[8, 7]; deficit-target separation1.226arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.657. Capable neighbours: Gaia 6057181524220240640: 15.16 arcsec, G14.357, required fractional eclipse0.197, pixel fractional loss0.011569246090371028; Gaia 6057181524220244480: 17.15 arcsec, G13.765, required fractional eclipse0.120, pixel fractional loss0.008403673294152252; Gaia 6057181524220244992: 19.43 arcsec, G14.081, required fractional eclipse0.156, pixel fractional loss0.008403673294152252; Gaia 6057181588591943552: 33.34 arcsec, G16.012, required fractional eclipse0.856, pixel fractional loss0.009381520926729047; Gaia 6057181592939737344: 36.01 arcsec, G15.802, required fractional eclipse0.708, pixel fractional loss0.010987593137566736; Gaia 6057178569282855936: 43.30 arcsec, G15.691, required fractional eclipse0.641, pixel fractional loss0.01054462829889948; Gaia 6057178603642493440: 58.22 arcsec, G15.236, required fractional eclipse0.426, pixel fractional loss-0.007294689097777693
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths11.569/10.998/10.078ppt, with 2 stacked events. QLP primary fitted median13.513ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR36057181524220247680, P=17.4320492926±0.0143074370d, e=0.491205, omega=74.2928deg. Closest edge-on conjunction offset0.009591d (0.000550phase), full-SB1-covariance linear propagated Gaia uncertainty0.611269d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.306923d (photometric period projection allowance0.006176d). The approximate central duration4.17h vs observed median4.39h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Attribution remains unresolved: seven capable neighbours include three within one TESS pixel (15.16, 17.15 and 19.43 arcsec); the historical PSF fractional residual is 0.657. A known Gaia eclipsing binary at 24.77 arcsec with P=0.312563 d is a different source, and its short period does not identify the 17.44 d signal. Real repeating eclipses pass the other checks; source localization is the failed scientific check. Resolved eclipse imaging or defensible multi-source PRF modeling is required.

Next check: Resolved eclipse photometry or multi-source PRF localization of the17.44d signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt
11	0	1604.0919255	0.010417	13.513
11	1	1621.5248445	0.010417	12.858
65	85	3086.1986389	0.001157	13.922

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, raw/QLP FITS; historical/diff_s11.json, historical/diff_s11.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 245474316: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors[58, 85]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=15.0172912209 ±0.0000236159d, reference primary epoch BTJD2884.3381092. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S58 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.339arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.251. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths211.230/200.007/179.092ppt, with 2 stacked events. QLP primary fitted median219.834ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3465063255000893824, P=15.0160303467±0.0023990301d, e=0.112486, omega=223.7112deg. Closest edge-on conjunction offset0.004132d (0.000275phase), full-SB1-covariance linear propagated Gaia uncertainty0.372564d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.205174d (photometric period projection allowance0.003920d). The approximate central duration10.65h vs observed median8.68h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated eclipses are isolated in both reductions; all four measured primary events support the timing solution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

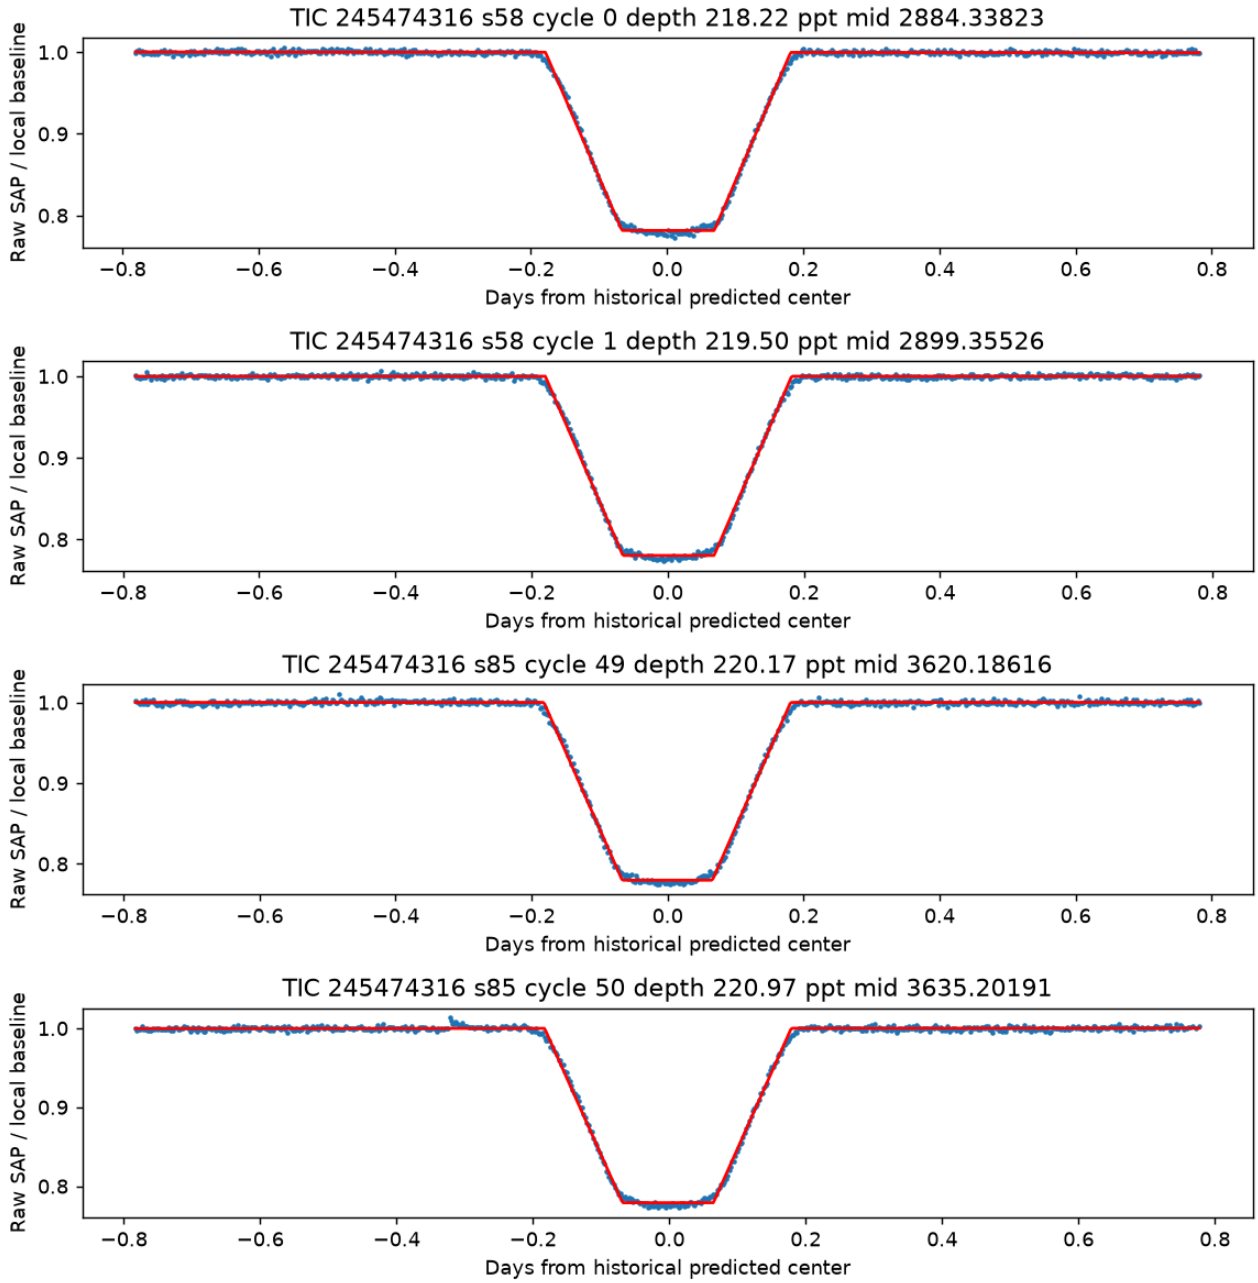
Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

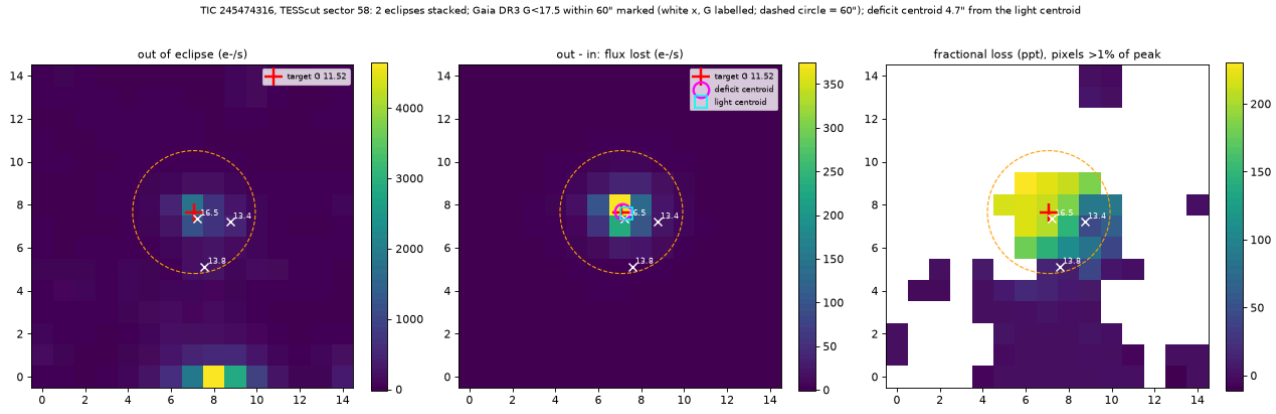
Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt
58	0	2884.3382264	0.001157	218.220
58	1	2899.3552650	0.001157	219.495
85	49	3620.1861623	0.001157	220.174
85	50	3635.2019054	0.001157	220.966

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, raw/QLP FITS; historical/diff_s58.json, historical/diff_s58.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R180. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R180; raw-events.png. Representative raw-flux eclipse windows; fitted timing and quality qualifications are in the report.



R180; diff_s58.png. Archived target-pixel eclipse-deficit evidence; capable-neighbour and resolution limitations remain as stated.

R181. TIC 397586559

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 397586559: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[42, 43, 70]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=9.8662883278 ±0.0000276603d, reference primary epoch BTJD2452.7124847. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S70 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation5.292arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.112. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths213.240/212.272/209.507ppt, with 5 stacked events. QLP primary fitted median253.719ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3275183241752731251 2, P=9.8675532753±0.0005013266d, e=0.011536, omega=68.9884deg. Closest edge-on conjunction offset-0.280929d (-0.028470phase), full-SB1-covariance linear propagated Gaia uncertainty0.101964d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.016555d (photometric period projection allowance0.005781d). The approximate central duration8.63h vs observed median6.97h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipses (primary median approximately254 ppt, secondary164 ppt) establish orbital period twice the historical4.93316d event spacing. Only deeper even cycles enter the reported primary ephemeris. Historical S70 difference image mixes both eclipse kinds, so its aperture depth is a mixture. Gaia nominal conjunction is0.28093d later at the TESS epoch; measured-Gaia period difference−0.00126495d accumulates this offset. Projecting toward the Gaia2016 reference reduces offset to−0.0166d; the orbit association is physically consistent with an imperfect Gaia period, and the tension is retained rather than subjected to a sigma veto.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 305801065: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors[15, 57, 85]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=6.0450293176 ±0.0000361616d, reference primary epoch BTJD1727.4094898. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S56 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation1.892arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.142. Capable neighbours: Gaia 2192612243770726016: 28.07 arcsec, G17.284, required fractional eclipse0.762, pixel fractional loss0.0049794454906507924; Gaia 2192612144989688192: 33.30 arcsec, G16.710, required fractional eclipse0.450, pixel fractional loss0.004025655733937976; Gaia 2192612144989688320: 54.57 arcsec, G16.272, required fractional eclipse0.302, pixel fractional loss0.0018812626929620051
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths4.343/4.217/4.030ppt, with 4 stacked events. QLP primary fitted median5.065ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR32192612213709164416, P=6.0451741506±0.0003743317d, e=0.037874, omega=130.3501deg. Closest edge-on conjunction offset-0.072174d (-0.011939phase), full-SB1-covariance linear propagated Gaia uncertainty0.076707d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.040166d (photometric period projection allowance0.007992d). The approximate central duration16.20h vs observed median5.48h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: The shallow eclipse is clearly repeated with localized ingress/egress despite higher scatter in newer sectors. Three capable neighbours at28.07,33.30,54.57arcsec are separated from the compact target deficit. Depth depends on dilution and trapezoid shape; historical median3.8ppt is not a precision intrinsic depth.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R183. TIC 345794632

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 345794632: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[15, 16, 83]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=14.6442648499 ±0.0000425120d, reference primary epoch BTJD1712.6089011. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S15 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.925arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.575. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths69.463/67.069/60.990ppt, with 2 stacked events. QLP primary fitted median73.387ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3197303850469635609 6, P=14.6450193761±0.0011842092d, e=0.123987, omega=43.5911deg. Closest edge-on conjunction offset-0.048332d (-0.003300phase), full-SB1-covariance linear propagated Gaia uncertainty0.120492d at the measured epoch. Near-Gaia-reference projected eclipse offset0.019576d (photometric period projection allowance0.003826d). The approximate central duration22.47h vs observed median12.91h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Large historical PSF fractional residual0.57 reflects imperfect scaled out-image morphology in a crowded field. No listed neighbour within60arcsec can supply the approximately73ppt eclipse under the G-band flux-budget screen, and the lost-light core coincides with the target. The weaker localization calibration remains a limitation.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R184. TIC 258621299

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 258621299: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 17 distinct eclipse events in selected sectors[20, 60, 73]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 9 same-kind midtimes give P=6.9859704688 ±0.0000173254d, reference primary epoch BTJD1845.3682206. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S20 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.195arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.058. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths143.337/141.526/141.187ppt, with 6 stacked events. QLP primary fitted median179.670ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3971297198904724608, P=6.9861245600±0.0003177162d, e=0.040129, omega=343.5407deg. Closest edge-on conjunction offset0.062467d (0.008942phase), full-SB1-covariance linear propagated Gaia uncertainty0.067290d at the measured epoch. Near-Gaia-reference projected eclipse offset0.094518d (photometric period projection allowance0.003604d). The approximate central duration8.56h vs observed median6.53h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipses (primary median approximately180ppt, secondary131ppt) establish orbital period twice the historical3.49299d event spacing. Only deeper even cycles enter the reported primary ephemeris. Historical S20 difference image mixes both eclipse kinds, so its aperture depth is a mixture.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R184; diff_s20.png. Archived target-pixel eclipse-deficit evidence; capable-neighbour and resolution limitations remain as stated.

R185. TIC 65346146

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 65346146: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[31, 97]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=10.6786239409 ±0.0000151247d, reference primary epoch BTJD2154.3895368. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S97 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.034arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.016. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths44.773/45.004/45.070ppt, with 3 stacked events. QLP primary fitted median38.206ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3507071941421676057 6, P=10.6786285931±0.0015065180d, e=0.189193, omega=56.2557deg. Closest edge-on conjunction offset0.051330d (0.004807phase), full-SB1-covariance linear propagated Gaia uncertainty0.259511d at the measured epoch. Near-Gaia-reference projected eclipse offset0.052098d (photometric period projection allowance0.002496d). The approximate central duration6.29h vs observed median5.65h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated flat-bottom eclipses; sector-dependent dilution changes fitted depths from about46 to38ppt.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R186. TIC 416646907

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 416646907: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 20 distinct eclipse events in selected sectors[31, 44, 71]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=6.3843147555 ±0.0000100738d, reference primary epoch BTJD2144.9943337. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S31 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.764arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.051. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths14.805/15.334/15.238ppt, with 7 stacked events. QLP primary fitted median17.963ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3109387319475984 64, P=6.3841880821±0.0003343665d, e=0.019823, omega=261.1834deg. Closest edge-on conjunction offset0.040618d (0.006362phase), full-SB1-covariance linear propagated Gaia uncertainty0.082376d at the measured epoch. Near-Gaia-reference projected eclipse offset0.005783d (photometric period projection allowance0.002770d). The approximate central duration9.19h vs observed median3.56h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Odd historical half-period cycles are deeper in each of three sectors (about18 versus16ppt); deeper odd cycles alone give the primary ephemeris and doubled orbital period. Alternative-reduction stack mixes eclipse kinds. Approximate central duration permits a noncentral chord.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 401138717: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 3 distinct eclipse events in selected sectors[38, 101]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=19.7928484049 ±0.0000402097d, reference primary epoch BTJD2338.1094210. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S38 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation2.355arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.976. Capable neighbours: Gaia 6059375874538434688: 36.73 arcsec, G13.483, required fractional eclipse0.726, pixel fractional loss0.012136886658324623; Gaia 6059374397069672832: 45.88 arcsec, G13.250, required fractional eclipse0.606, pixel fractional loss0.0003268121523994738; Gaia 6059374397069669504: 55.21 arcsec, G8.266, required fractional eclipse0.111, pixel fractional loss0.00037149356202306885
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths70.076/37.681/12.642ppt, with 2 stacked events. QLP primary fitted median111.598ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3605937594325792000, P=19.7872890022±0.0033433246d, e=0.337643, omega=172.1929deg. Closest edge-on conjunction offset0.616978d (0.031181phase), full-SB1-covariance linear propagated Gaia uncertainty0.285169d at the measured epoch. Near-Gaia-reference projected eclipse offset0.072157d (photometric period projection allowance0.003941d). The approximate central duration13.30h vs observed median9.30h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Three capable neighbours and high scaled-out-image residual0.976 limit PSF precision. Target-centered compact loss and aperture-depth growth support attribution. Known EB42.73arcsec away has P0.363740d, distinct from19.79d. Gaia period differs by0.00556d, accounting for much of the accumulated conjunction offset; this physical tension is retained.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

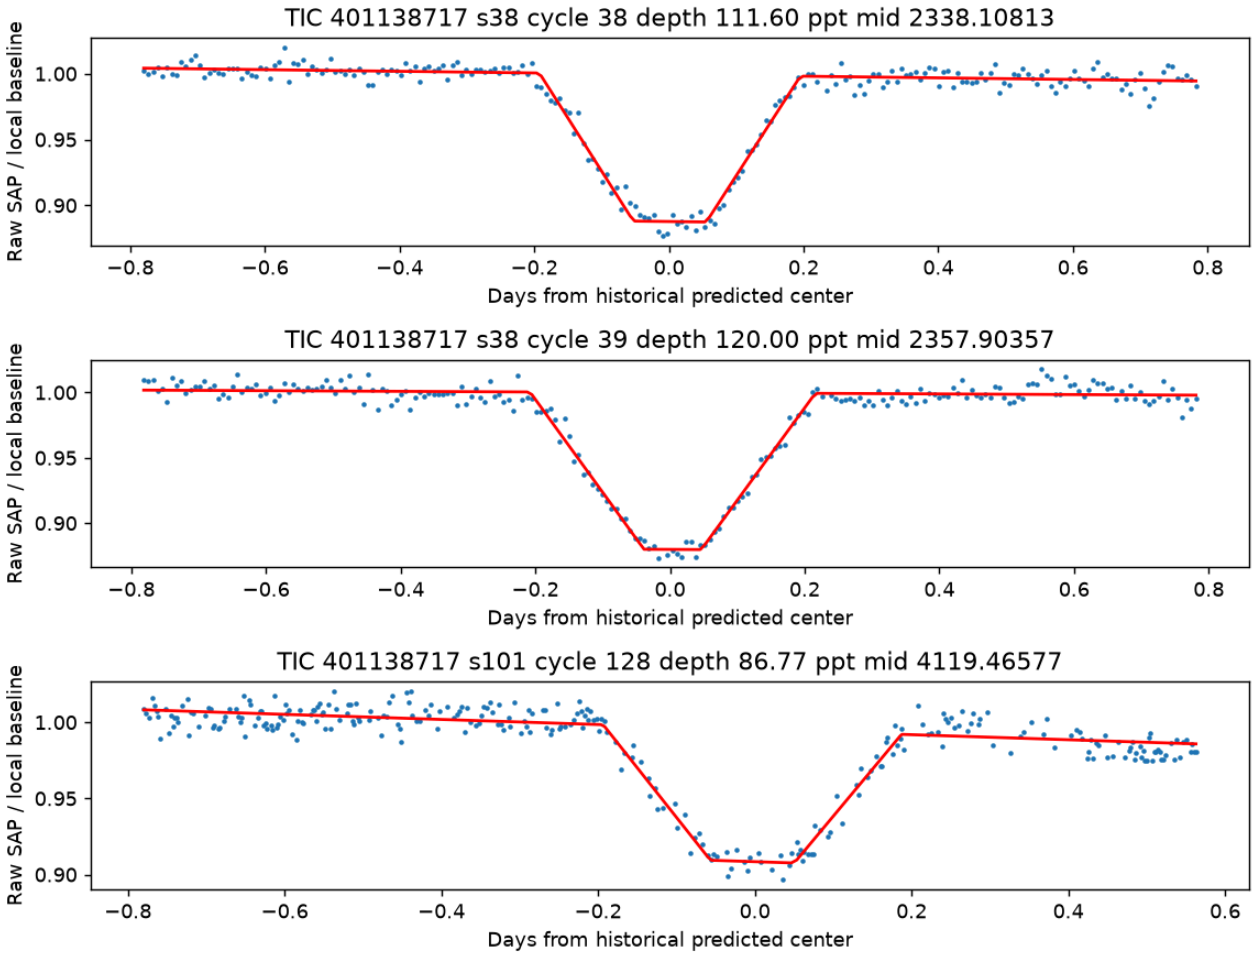
Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt
38	38	2338.1081311	0.003472	111.598
38	39	2357.9035737	0.003472	120.005
101	128	4119.4657691	0.002631	86.769

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, ../../shared-qlp/QLP FITS; historical/diff_s38.json, historical/diff_s38.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R187. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R187; raw-events.png. Representative raw-flux eclipse windows; fitted timing and quality qualifications are in the report.

Archived source: sanitized report text.

TIC 334379409: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 15 distinct eclipse events in selected sectors[20, 60, 74]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 15 same-kind midtimes give P=3.9471266750 ±0.0000086262d, reference primary epoch BTJD1846.4992369. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S20 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.967arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.052. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths8.815/9.122/9.021ppt, with 6 stacked events. QLP primary fitted median9.703ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3108412255379619660 8, P=3.9478875756±0.0002427008d, e=0.119742, omega=0.8238deg. Closest edge-on conjunction offset-0.086809d (-0.021989phase), full-SB1-covariance linear propagated Gaia uncertainty0.086629d at the measured epoch. Near-Gaia-reference projected eclipse offset0.193963d (photometric period projection allowance0.003183d). The approximate central duration6.43h vs observed median4.49h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated raw eclipses have modest baseline variability. Gaia period mismatch accumulates over the baseline; propagated covariance and conjunction comparison are descriptive rather than a sigma threshold.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R189. TIC 345406164

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 345406164: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors[54, 81]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=7.4405907450 ±0.0000495074d, reference primary epoch BTJD2771.4040073. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S81 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.076arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.319. Capable neighbours: Gaia 4237461433423122688: 7.77 arcsec, G12.987, required fractional eclipse0.337, pixel fractional loss0.039804052005913027; Gaia 4237461639581556992: 39.85 arcsec, G14.229, required fractional eclipse0.903, pixel fractional loss0.012143463390351002; Gaia 4237462910891870720: 46.38 arcsec, G13.638, required fractional eclipse0.554, pixel fractional loss0.005077976710626553
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths39.804/40.512/36.074ppt, with 5 stacked events. QLP primary fitted median74.892ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3423746143342312153 6, P=7.4404803638±0.0003387583d, e=0.018421, omega=297.4883deg. Closest edge-on conjunction offset0.055481d (0.007457phase), full-SB1-covariance linear propagated Gaia uncertainty0.115704d at the measured epoch. Near-Gaia-reference projected eclipse offset0.020159d (photometric period projection allowance0.015842d). The approximate central duration9.03h vs observed median5.08h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deeper even cycles near75ppt alternate with47ppt odd eclipses in sector81, establishing doubled orbital period. Primary-only ephemeris used. Historical stack mixes eclipse kinds. Three capable neighbours are away from compact target deficit.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 152400959: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[7, 34, 88]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=5.5128574495 ±0.0000063398d, reference primary epoch BTJD1492.1132318. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S7 deficit peak[8, 8] vs target pixel[8, 7]; deficit-target separation4.210arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.959. Capable neighbours: Gaia 5594494902225244160: 55.47 arcsec, G10.157, required fractional eclipse0.066, pixel fractional loss0.0003869186084721213; Gaia 5594494902225244672: 58.02 arcsec, G10.321, required fractional eclipse0.068, pixel fractional loss0.0003869186084721213
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths50.239/25.011/9.987ppt, with 4 stacked events. QLP primary fitted median54.372ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3559449527587867763 2, P=5.5134762690±0.0002135603d, e=0.241108, omega=1.8534deg. Closest edge-on conjunction offset-0.071963d (-0.013052phase), full-SB1-covariance linear propagated Gaia uncertainty0.052295d at the measured epoch. Near-Gaia-reference projected eclipse offset0.051801d (photometric period projection allowance0.001268d). The approximate central duration5.76h vs observed median3.98h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Known EB27.09arcsec away at0.257384d differs from5.513d signal. Two capable neighbours and residual0.959 limit PSF precision; compact target-centered deficit and small-aperture eclipse support attribution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R191. TIC 152086769

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 152086769: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 9 distinct eclipse events in selected sectors[2, 69, 96]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 9 same-kind midtimes give P=6.3322039761 ±0.0000079047d, reference primary epoch BTJD1356.8092972. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S29 deficit peak[8, 8] vs target pixel[8, 7]; deficit-target separation0.183arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.783. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths263.413/258.932/233.354ppt, with 3 stacked events. QLP primary fitted median279.743ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3234049886410287782 4, P=6.3321286286±0.0002353598d, e=0.041230, omega=343.5423deg. Closest edge-on conjunction offset0.064331d (0.010159phase), full-SB1-covariance linear propagated Gaia uncertainty0.053697d at the measured epoch. Near-Gaia-reference projected eclipse offset0.052803d (photometric period projection allowance0.001209d). The approximate central duration5.90h vs observed median4.83h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep flat-bottom repeated eclipses; sector96 aperture depth is lower than earlier sectors. No capable neighbour within60arcsec in approximate G flux budget.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 270260727: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors[67, 95]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=10.2916499025 ±0.0000194560d, reference primary epoch BTJD3129.8498677. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S27 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.281arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.715. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths4.589/5.482/5.221ppt, with 2 stacked events. QLP primary fitted median5.805ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3637722980402626918 4, P=10.2925042178±0.0014381993d, e=0.316068, omega=77.3278deg. Closest edge-on conjunction offset-0.205903d (-0.020005phase), full-SB1-covariance linear propagated Gaia uncertainty0.368617d at the measured epoch. Near-Gaia-reference projected eclipse offset0.021344d (photometric period projection allowance0.005175d). The approximate central duration4.34h vs observed median1.86h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Shallow localized repeated eclipses are resolved in sectors67 and95; raw scatter and trapezoid approximation limit precision. No capable neighbour within60arcsec under G flux budget.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt
67	175	3129.8487012	0.001528	6.462
67	177	3150.4343910	0.001549	6.206
95	249	3891.4325817	0.001523	5.403
95	250	3901.7232234	0.001180	5.378

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, ../../shared-qlp/QLP FITS; historical/diff_s27.json, historical/diff_s27.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. TIC 112827464: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[67, 94]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=3.4225952625 ±0.0000046565d, reference primary epoch BTJD3129.3941410. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S27 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation3.053arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.582. Capable neighbours: Gaia 6744219263229275136: 30.53 arcsec, G12.650, required fractional eclipse0.115, pixel fractional loss0.003067157147837522
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths30.267/25.168/18.244ppt, with 6 stacked events. QLP primary fitted median33.456ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR36744219095727246720, P=3.4231233978±0.0002361926d, e=0.285125, omega=17.3840deg. Closest edge-on conjunction offset-0.215585d (-0.062979phase), full-SB1-covariance linear propagated Gaia uncertainty0.164184d at the measured epoch. Near-Gaia-reference projected eclipse offset0.207452d (photometric period projection allowance0.003730d). The approximate central duration4.26h vs observed median3.16h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Raw local baseline slopes are fitted explicitly. One capable neighbour is separated from the target-centered deficit; no calibrated centroid confidence ellipse. Gaia nominal phase offset0.063 and period drift remain explicit; full covariance and near-reference projection support association without arbitrary sigma veto.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 423657976: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[37, 64]. The lead inspected raw-event plots and numeric fitting summaries. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=6.6164167932 ±0.0000164775d, reference primary epoch BTJD2310.5996711. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S37 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.183arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.050. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths84.471/82.835/81.952ppt, with 4 stacked events. QLP primary fitted median93.973ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3619478907657997 2992, P=6.6172062581±0.0008867054d, e=0.023556, omega=59.1528deg. Closest edge-on conjunction offset-0.245165d (-0.037050phase), full-SB1-covariance linear propagated Gaia uncertainty0.251243d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.016220d (photometric period projection allowance0.004778d). The approximate central duration5.70h vs observed median4.00h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated eclipses with stable approximately94ppt QLP depth. No capable neighbour within60arcsec under approximate G flux budget.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R195. TIC 343926224

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 343926224: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors [15, 76, 84]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=10.7289779063 ±0.0001985830 d, reference primary epoch BTJD 1716.2856364. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S76 deficit peak [8, 7] vs target pixel [8, 7]; deficit-target separation 1.439 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.350. Capable neighbours: Gaia 2189412291279426432: 55.00 arcsec, G 13.916, required fractional eclipse 0.414, pixel fractional loss 0.003238694850407246
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 34.297/34.868/34.349 ppt, with 3 stacked events. QLP primary fitted median 42.292 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 2189412256919685888, P=10.7249538611±0.0028660106 d, e=0.214758, omega=124.7057 deg. Closest edge-on conjunction offset 0.251123 d (0.023415 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.280852 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.247858 d (photometric period projection allowance 0.024624 d). The approximate central duration 11.18 h vs median local-model width 7.49 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Five clean primary repeats determine the ephemeris. S76 historical cycle 154 has structured excursions and an anomalously weak fitted dip; S84 cycle 176 has a broad distorted profile. Both remain in raw-windows.csv and plots but are excluded from the timing fit. The capable neighbour at 55.00 arcsec is separated from the compact target deficit. Aperture and local baseline variations limit depth precision. The retained timing fit has reduced chi-square 18.08; residual timing scatter materially inflates the stated period error and shows model/baseline limitations.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R196. TIC 53993311

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 53993311: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors [68, 95]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=14.5428334094 ±0.0000231439 d, reference primary epoch BTJD 3157.6706598. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S28 deficit peak [7, 7] vs target pixel [7, 7]; deficit-target separation 1.428 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.035. Capable neighbours: None within 60 arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 102.900/102.856/101.894 ppt, with 2 stacked events. QLP primary fitted median 97.186 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 6812467324352893952, P=14.5383792659±0.0050945887 d, e=0.043960, omega=139.8471 deg. Closest edge-on conjunction offset 0.707888 d (0.048691 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.958534 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.138399 d (photometric period projection allowance 0.004397 d). The approximate central duration 8.24 h vs median local-model width 7.11 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Aperture-dependent primary depth changes from about 107 ppt in S68 to 85 ppt in S95; the same localized eclipse morphology repeats. Gaia conjunction uncertainty is substantial; a phase offset alone is not a veto.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt
68	125	3157.6707302	0.001157	107.223
68	126	3172.2134177	0.001157	106.957
95	175	3884.8125205	0.001157	87.415
95	176	3899.3549786	0.001157	84.684

Archived source: sanitized report text.

TIC 43785616: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors [5, 32]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=17.9111228161 ±0.0001892149 d, reference primary epoch BTJD 1440.8508244. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S5 deficit peak [8, 8] vs target pixel [8, 8]; deficit-target separation 5.190 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.368. Capable neighbours: None within 60 arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 24.513/24.741/24.787 ppt, with 2 stacked events. QLP primary fitted median 23.115 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 3182410104496905344, P=17.9129197903±0.0059901956 d, e=0.050997, omega=88.2029 deg. Closest edge-on conjunction offset -0.515453 d (-0.028776 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.440210 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.409432 d (photometric period projection allowance 0.011164 d). The approximate central duration 6.54 h vs median local-model width 9.12 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Observed trapezoid duration exceeds a central estimate based on default primary mass and minimum companion mass. That approximate estimate is not an upper bound: stellar properties and inclination are not fitted. Repeated flat-bottomed events and matching period support association; detailed binary modeling remains optional.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R198. TIC 397178704

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 397178704: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors [10, 37, 90]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=11.0096850472 ±0.0000177172 d, reference primary epoch BTJD 1578.4727019. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S65 deficit peak [8, 7] vs target pixel [8, 7]; deficit-target separation 2.858 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.676. Capable neighbours: Gaia 5233172429035086848: 45.82 arcsec, G 12.303, required fractional eclipse 0.467, pixel fractional loss 0.014161864689712712
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 153.625/140.797/97.827 ppt, with 4 stacked events. QLP primary fitted median 175.670 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 5233172532114305408, P=11.0086850571±0.0011569463 d, e=0.075755, omega=344.1277 deg. Closest edge-on conjunction offset 0.262492 d (0.023844 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.142187 d at the measured epoch. Near-Gaia-reference projected eclipse offset 0.154493 d (photometric period projection allowance 0.001913 d). The approximate central duration 10.12 h vs median local-model width 7.11 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating primary and secondary eclipses establish twice the historical 5.50484 d event spacing. Only deeper odd cycles enter the primary ephemeris. The historical stack mixes both kinds. Large PSF residual 0.676 reflects surrounding light rather than an off-target core; the one capable neighbour lies 45.82 arcsec away from the compact deficit.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

R199. TIC 77550184

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 77550184: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors [8, 35, 99]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=10.2144162596 ±0.0000141900 d, reference primary epoch BTJD 1527.7251647. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S8 deficit peak [8, 8] vs target pixel [8, 8]; deficit-target separation 0.736 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.079. Capable neighbours: None within 60 arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 59.400/58.814/57.033 ppt, with 2 stacked events. QLP primary fitted median 60.644 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 3840677541266884352, P=10.2148324921±0.0012985204 d, e=0.011129, omega=282.6369 deg. Closest edge-on conjunction offset 0.009445 d (0.000925 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.191111 d at the measured epoch. Near-Gaia-reference projected eclipse offset 0.055647 d (photometric period projection allowance 0.001575 d). The approximate central duration 8.78 h vs median local-model width 7.37 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated eclipses have aperture-dependent depths of approximately 56 to 63 ppt. No capable neighbour lies within the 60 arcsec screen.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 314041837: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 13 distinct eclipse events in selected sectors [17, 77, 85]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 13 same-kind midtimes give P=4.4779956510 ±0.0000153414 d, reference primary epoch BTJD 1770.0417343. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S24 deficit peak [7, 7] vs target pixel [7, 7]; deficit-target separation 5.683 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.595. Capable neighbours: Gaia 2013547914676675456: 27.40 arcsec, G 14.937, required fractional eclipse 0.684, pixel fractional loss 0.020156189636425306; Gaia 2013547090042960640: 53.17 arcsec, G 14.840, required fractional eclipse 0.628, pixel fractional loss 0.0038196993836605766
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 30.364/29.166/27.018 ppt, with 6 stacked events. QLP primary fitted median 44.521 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 2013547154462321152, P=4.4771653875±0.0004155553 d, e=0.092195, omega=238.1338 deg. Closest edge-on conjunction offset 0.076024 d (0.016980 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.117104 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.179697 d (photometric period projection allowance 0.004725 d). The approximate central duration 15.94 h vs median local-model width 18.79 h is only an approximate comparison; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: The target is a large star (TIC radius 5.09 solar radii) with ellipsoidal modulation plus localized eclipses. A two-harmonic baseline fitted outside the primary core in S77 leaves a 30.31 ppt localized deficit; its double-wave modulation does not explain the eclipse. See harmonic-test.json and png. The 18.79 h local-linear trapezoid width includes smooth variability and is not a physical eclipse duration. The reported depth likewise describes that local model, not intrinsic eclipse depth. Capable neighbours at 27.40 and 53.17 arcsec are away from the target-centered deficit; PSF residual 0.595 limits morphology precision.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R201. TIC 7446763

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 7446763: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 23 distinct eclipse events in selected sectors [4, 32, 98]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 12 same-kind midtimes give P=5.9119066682 ±0.0000054818 d, reference primary epoch BTJD 1415.6444465. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S98 deficit peak [8, 7] vs target pixel [8, 7]; deficit-target separation 1.268 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.099. Capable neighbours: None within 60 arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 52.841/52.588/50.932 ppt, with 17 stacked events. QLP primary fitted median 72.076 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 4798935876591849088, P=5.9116154455±0.0003030802 d, e=0.013640, omega=116.4877 deg. Closest edge-on conjunction offset 0.070541 d (0.011933 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.077901 d at the measured epoch. Near-Gaia-reference projected eclipse offset 0.019868 d (photometric period projection allowance 0.000954 d). The approximate central duration 9.34 h vs median local-model width 7.52 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Primary eclipses are approximately twice secondary depth. Only deeper odd historical half-period cycles determine the ephemeris; the reported orbital period doubles the historical 2.95595 d spacing. Historical S98 aperture stack mixes both eclipse kinds.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 22705959: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors [20, 47, 60]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=11.3768104522 ±0.0000570223 d, reference primary epoch BTJD 1843.6400352. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S20 deficit peak [7, 8] vs target pixel [8, 8]; deficit-target separation 3.640 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.275. Capable neighbours: Gaia 930540059504937344: 39.75 arcsec, G 13.434, required fractional eclipse 0.884, pixel fractional loss 0.0327311642163424
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 133.056/122.988/111.050 ppt, with 2 stacked events. QLP primary fitted median 140.885 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 930540158288480128, P=11.3782568753±0.0013112244 d, e=0.042943, omega=14.8614 deg. Closest edge-on conjunction offset -0.160237 d (-0.014083 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.150148 d at the measured epoch. Near-Gaia-reference projected eclipse offset 0.024905 d (photometric period projection allowance 0.007299 d). The approximate central duration 7.23 h vs median local-model width 6.02 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: A capable neighbour at 39.75 arcsec is separated from the target deficit. The target sits near a pixel boundary: the global deficit peak rounds to an adjacent pixel, while the centroid is only 3.64 arcsec from the actual target. This is not evidence for a different source.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R203. TIC 62940616

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 62940616: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors [46, 72]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=4.9985872939 ±0.0000131921 d, reference primary epoch BTJD 2556.4440266. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S46 deficit peak [8, 7] vs target pixel [8, 7]; deficit-target separation 4.310 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.145. Capable neighbours: Gaia 3600574305187842176: 22.67 arcsec, G 13.447, required fractional eclipse 0.329, pixel fractional loss 0.04157460368672594
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 47.812/44.599/42.097 ppt, with 4 stacked events. QLP primary fitted median 52.594 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 3600574305187842304, P=4.9982995596±0.0002208867 d, e=0.031476, omega=231.2156 deg. Closest edge-on conjunction offset 0.087414 d (0.017489 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.100248 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.037462 d (photometric period projection allowance 0.005725 d). The approximate central duration 6.60 h vs median local-model width 4.91 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: One capable neighbour at 22.67 arcsec requires a 0.329 fractional eclipse to explain the signal, but the lost-light centroid lies 0.205 pixel from the target versus 1.33 pixels from that neighbour, displaced away from it. Its pixel fractional loss 0.0416 is a blended-pixel value and does not measure the neighbour intrinsic eclipse depth. The target-centered depth increases in the 1x1 aperture, consistent with target dilution in larger apertures. TESS resolution and G-to-TESS colour differences limit attribution precision.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R203; diff_s46.png. Archived target-pixel eclipse-deficit evidence; capable-neighbour and resolution limitations remain as stated.

R204. TIC 100911870

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 100911870: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors [56, 83]. The lead inspected the raw-event contact plot and numeric fit output. All fitted windows are preserved, including excluded anomalous windows described below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=12.6370024218 ±0.0000199523 d, reference primary epoch BTJD 2833.8497257. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S56 deficit peak [8, 8] vs target pixel [8, 8]; deficit-target separation 1.475 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.035. Capable neighbours: None within 60 arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 81.281/81.747/81.121 ppt, with 2 stacked events. QLP primary fitted median 84.035 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 1910795941713925248, P=12.6391809008±0.0017180040 d, e=0.482982, omega=164.1837 deg. Closest edge-on conjunction offset -0.236653 d (-0.018724 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.328560 d at the measured epoch. Near-Gaia-reference projected eclipse offset 0.183794 d (photometric period projection allowance 0.003851 d). The approximate central duration 8.21 h vs median local-model width 6.03 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four clean primary events in S56 and S83 support the timing solution and approximately 84 ppt raw QLP depth. No capable neighbour is present in the 60 arcsec screen.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

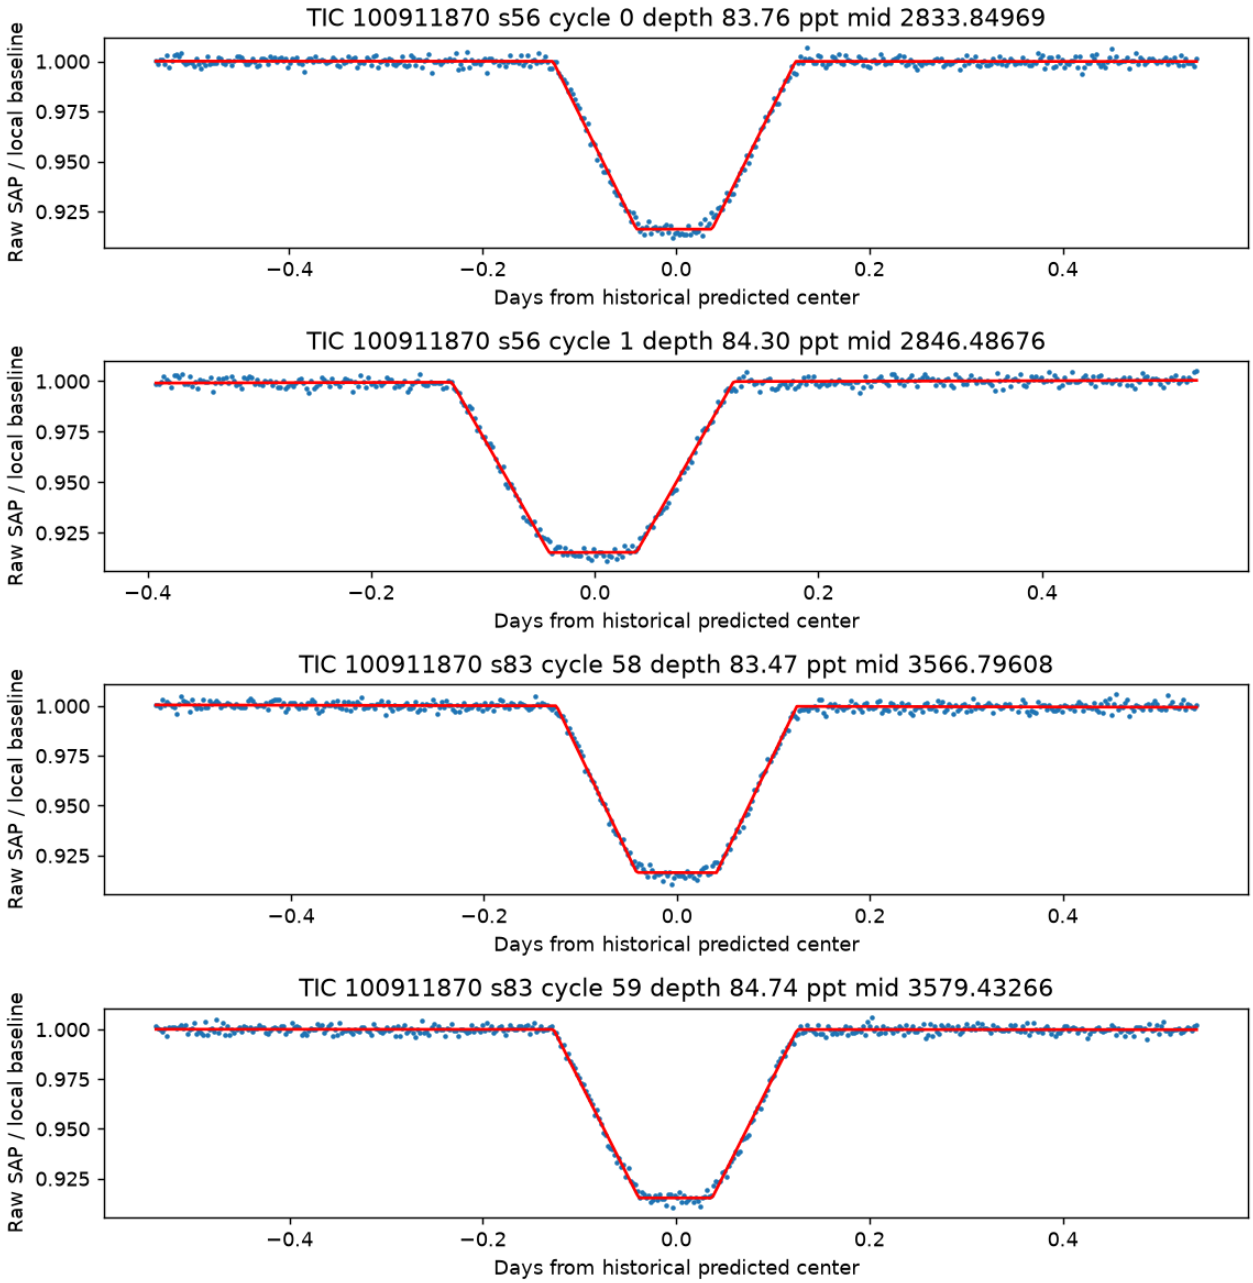
Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

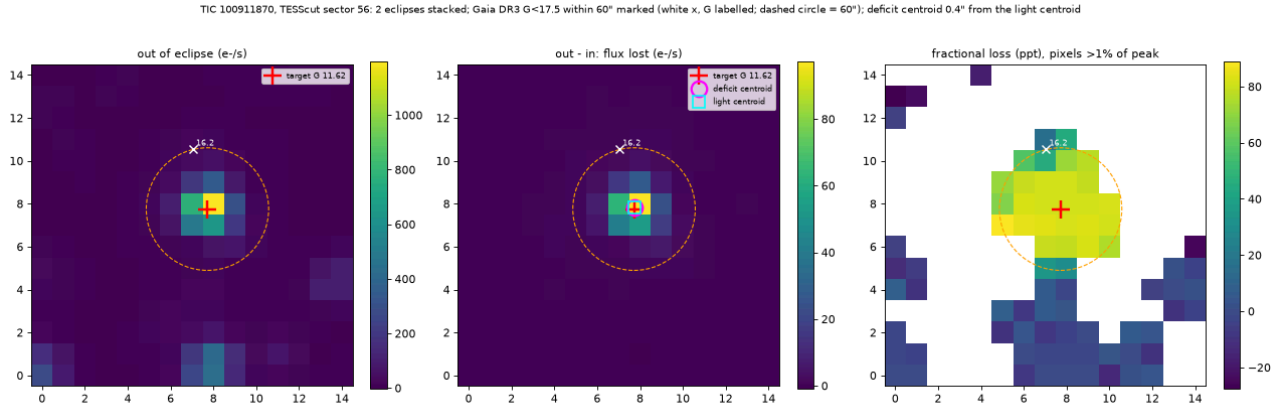
Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt
56	0	2833.8496949	0.001157	83.765
56	1	2846.4867559	0.001157	84.304
83	58	3566.7960765	0.001157	83.470
83	59	3579.4326614	0.001157	84.744

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, ../../shared-qlp QLP FITS; historical/diff_s56.json, historical/diff_s56.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R204. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R204; raw-events.png. Representative raw-flux eclipse windows; fitted timing and quality qualifications are in the report.



R204; diff_s56.png. Archived target-pixel eclipse-deficit evidence; capable-neighbour and resolution limitations remain as stated.

R205. TIC 77176486

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 77176486: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors [31, 98]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [53, 54, 187, 189, 190]; excluded cycles [188] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 retained reference-eclipse midtimes give P=13.7536919134 +/-0.0000189931 d, observed reference eclipse epoch BTJD 2153.3151206. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S98 deficit peak [8, 8] vs target pixel [8, 8]; deficit-target separation 1.800 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.289. Capable neighbours: Gaia 4864096337267522304: 30.54 arcsec, G 15.883, required fractional eclipse 0.724, pixel fractional loss 0.013984958972541156; Gaia 4864096268548045056: 55.77 arcsec, G 13.048, required fractional eclipse 0.066, pixel fractional loss 0.0017051419244163086
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 14.204/14.336/12.592 ppt, with 3 stacked events. QLP retained-reference fitted median 12.944 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 4864096337267521536, P=13.7484948196+/-0.0039618290 d, e=0.036317, omega=108.4415 deg. Closest edge-on conjunction offset 0.578516 d (0.042078 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.549110 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.086712 d (photometric period projection allowance 0.002431 d). The approximate central

duration 7.94 h vs median local-model width 7.79 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: The 13.75369 d signal lies near the TESS orbital timescale, but repeated localized raw SAP dips in S31 and S98 and the target-centered cutout deficit support astrophysical eclipses. Quality-nonzero cadences are excluded; no flagged or uncovered window is a clean null. Cycle188 is visibly present but its trapezoid covariance is singular, so it is excluded from timing. Bounded S98 pixel/background check (background-check.json) finds target-pixel losses11.99/22.43/16.35 electrons/s versus3.24/9.85/7.73 at the close capable neighbour and0.70/6.30/3.36 at the farther one. Outer-pixel median losses are -0.027/5.68/4.04: common-mode background affects later events, while cycle187 is localized with negligible outer deficit. Core quality flags are0/0/3; flagged cadences are excluded. FLUX_BKG is zero throughout and supplies no independent background measurement. These are descriptive diagnostics, not a calibrated artifact veto. Gaia conjunction offset is 0.04208 phase with 0.549 d propagated uncertainty; this is association support with appreciable orbital uncertainty, not a precise phase coincidence.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R206. TIC 155916287

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 155916287: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors [16, 50, 77]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [0, 1, 2, 3, 154, 156, 275]; excluded cycles [] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 retained reference-eclipse midtimes give P=6.0531543976 +/-0.0000154319 d, observed reference eclipse epoch BTJD 1741.6770525. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S51 deficit peak [7, 7] vs target pixel [7, 7]; deficit-target separation 1.896 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.052. Capable neighbours: None within 60 arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 31.135/30.140/29.786 ppt, with 3 stacked events. QLP retained-reference fitted median 31.520 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 1585947494733568128, P=6.0530078707+/-0.0002180703 d, e=0.153531, omega=253.9761 deg. Closest edge-on conjunction offset -0.054876 d (-0.009066 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.053462 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.087551 d (photometric period projection allowance 0.003441 d). The approximate central duration 4.41 h vs median local-model width 2.01 h is only an approximate comparison; this

radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Seven fitted repeats span S16,50,77. Sector-dependent depth variation and long-cadence integration limit intrinsic depth and duration precision.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 383603595: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors [8, 62, 90]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [0, 1, 294, 295, 296, 297, 445, 446, 447, 448, 449]; excluded cycles [] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 retained reference-eclipse midtimes give P=5.0148153412 +/-0.0000049551 d, observed reference eclipse epoch BTJD 1520.2020452. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S89 deficit peak [8, 8] vs target pixel [8, 8]; deficit-target separation 0.862 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.931. Capable neighbours: Gaia 5303521141484894592: 9.86 arcsec, G 15.271, required fractional eclipse 0.881, pixel fractional loss 0.02715275445324021; Gaia 5303521137176600576: 16.56 arcsec, G 14.623, required fractional eclipse 0.499, pixel fractional loss 0.021045342368154214; Gaia 5303521038405677568: 24.30 arcsec, G 15.129, required fractional eclipse 0.777, pixel fractional loss 0.02056002298778204; Gaia 5303521141484897664: 56.62 arcsec, G 15.396, required fractional eclipse 0.985, pixel fractional loss 0.003267899249113125; Gaia 5303521210204372224: 58.12 arcsec, G 15.245, required fractional eclipse 0.862, pixel fractional loss 0.0008082498493232974
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 27.153/24.924/19.335 ppt, with 6 stacked events. QLP retained-reference fitted median 32.026 ppt. This separately extracted cutout is an alternative reduction of the same TESS

photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3 5303521038405679232, P=5.0148048769+/-0.0002225298 d, e=0.018777, omega=298.0394 deg. Closest edge-on conjunction offset 0.000726 d (0.000145 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.056590 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.001639 d (photometric period projection allowance 0.001120 d). The approximate central duration 5.55 h vs median local-model width 2.88 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Eleven fitted repeated eclipses span S8,62,90. Modest aperture/baseline depth variation limits precision; no missing bounded check.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 436724968: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 23 distinct eclipse events in selected sectors [43, 44, 71]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [0, 1, 2, 3, 5, 6, 7, 8, 10, 11, 12, 13, 15, 16, 17, 279, 280, 281, 282, 284, 285, 286, 287]; excluded cycles [] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 23 retained reference-eclipse midtimes give P=2.7321550784 +/-0.0000037340 d, observed reference eclipse epoch BTJD 2475.2746864. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S43 deficit peak [7, 7] vs target pixel [7, 7]; deficit-target separation 5.654 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.458. Capable neighbours: Gaia 3405581312479002624: 35.19 arcsec, G 13.629, required fractional eclipse 0.317, pixel fractional loss 0.007404879626139636; Gaia 3405581308183975552: 35.89 arcsec, G 12.381, required fractional eclipse 0.130, pixel fractional loss 0.007404879626139636
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 41.459/36.665/28.902 ppt, with 8 stacked events. QLP retained-reference fitted median 48.530 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 3405581312480317184, P=2.7321672331+/-0.0000779633 d, e=0.019821, omega=313.1687 deg. Closest edge-on conjunction offset 0.004140 d (0.001515 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.059868 d at the measured epoch. Near-Gaia-reference projected eclipse offset

0.013426 d (photometric period projection allowance 0.002853 d). The approximate central duration 5.02 h vs median local-model width 2.87 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: QLP free-trapezoid depths show modest parity differences, especially in S71; local baseline and aperture dependence are material. Independent S43 3x3 cutout depths are 35.34-37.19 ppt for eight events including consecutive odd/even cycles, without a stable unequal alternating pattern. Gaia P=2.732167 d matches the measured event spacing. These data do not establish two distinct alternating eclipse kinds or require doubling; report the fitted period as the adopted orbit with this depth-model limitation, and the epoch as an observed reference eclipse. Capable neighbours at 35.19 and 35.89 arcsec are displaced from the compact target deficit.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 37948318: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 9 distinct eclipse events in selected sectors [5, 32, 98]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [0, 1, 2, 91, 317, 319, 321, 322]; excluded cycles [93] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 retained reference-eclipse midtimes give P=8.0567270177 +/-0.0000120865 d, observed reference eclipse epoch BTJD 1444.2226216. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S98 deficit peak [8, 7] vs target pixel [7, 7]; deficit-target separation 15.096 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.197. Capable neighbours: Gaia 3191831957073992960: 53.65 arcsec, G 13.726, required fractional eclipse 0.080, pixel fractional loss 0.0009833145507867729
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 11.870/11.463/10.353 ppt, with 6 stacked events. QLP retained-reference fitted median 11.182 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 3191832060153207296, P=8.0560480995+/-0.0007371091 d, e=0.027806, omega=108.0360 deg. Closest edge-on conjunction offset 0.067844 d (0.008422 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.109490 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.021094 d (photometric period projection allowance 0.001583 d). The approximate central

duration 8.86 h vs median local-model width 3.58 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: The historical absolute target-to-deficit offset is 15.1 arcsec (0.719 pixel), while light-to-deficit separation is 3.51 arcsec; these are distinct comparisons. The capable G13.73 neighbour is 53.65 arcsec away and opposite the deficit displacement. Independent per-event pixel checks find target-pixel losses 9.03-10.59 electrons/s against 0.185-0.437 at that neighbour in cycles317,319,321. This supports the target over the capable neighbour at TESS resolution, with an uncalibrated absolute-centroid systematic and residual crowding uncertainty. Historical cycles316/318 have common-mode excursions and are not individually decisive. QLP cycle93 has singular timing covariance and is excluded from timing.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 373034189: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors [10, 38, 90]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [-1, 58, 59, 168]; excluded cycles [] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 retained reference-eclipse midtimes give P=12.9887040978 +/-0.0000284334 d, observed reference eclipse epoch BTJD 1571.7245142. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S37 deficit peak [8, 8] vs target pixel [8, 8]; deficit-target separation 1.843 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.602. Capable neighbours: Gaia 5244879719604788736: 12.97 arcsec, G 16.354, required fractional eclipse 0.981, pixel fractional loss 0.01193560877869184; Gaia 5244879685245057792: 26.35 arcsec, G 16.047, required fractional eclipse 0.743, pixel fractional loss 0.009390864249180396; Gaia 5244879753964534272: 39.11 arcsec, G 14.573, required fractional eclipse 0.201, pixel fractional loss 0.0011670286575604556; Gaia 5244879749658927872: 41.19 arcsec, G 16.027, required fractional eclipse 0.730, pixel fractional loss 0.0021282245777576024; Gaia 5244879685245061120: 49.50 arcsec, G 15.334, required fractional eclipse 0.391, pixel fractional loss 0.002861556685359608; Gaia 5244879753964537088: 55.03 arcsec, G 13.752, required fractional eclipse 0.101, pixel fractional loss 0.0011670286575604556; Gaia 5244879685245061248: 55.94 arcsec, G 14.789, required fractional eclipse 0.242, pixel fractional loss 0.002861556685359608; Gaia 5244880475519027968: 58.01 arcsec, G 15.671, required fractional eclipse 0.529, pixel fractional loss 0.008261259167357336

4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 12.011/11.765/10.114 ppt, with 2 stacked events. QLP retained-reference fitted median 12.696 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 5244879715298215680, P=12.9859550458+/-0.0027301281 d, e=0.173284, omega=212.5666 deg. Closest edge-on conjunction offset 0.131586 d (0.010133 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.310452 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.118577 d (photometric period projection allowance 0.002587 d). The approximate central duration 10.74 h vs median local-model width 4.72 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four raw fitted eclipses in S10,38,90 support the period. The Gaia conjunction uncertainty is substantial (0.3105 d); local model widths and depths are descriptive.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 300969635: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors [1, 37, 98]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [0, 1, 2, 3, 133, 134, 135, 360, 362, 364, 366]; excluded cycles [] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 retained reference-eclipse midtimes give P=7.4207275328 +/-0.0000078157 d, observed reference eclipse epoch BTJD 1328.2542487. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S33 deficit peak [7, 8] vs target pixel [7, 8]; deficit-target separation 3.496 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.657. Capable neighbours: None within 60 arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 213.987/196.358/182.802 ppt, with 4 stacked events. QLP retained-reference fitted median 217.538 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 5270681477928794752, P=7.4211188474+/-0.0005357254 d, e=0.017042, omega=195.0962 deg. Closest edge-on conjunction offset -0.058560 d (-0.007891 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.073044 d at the measured epoch. Near-Gaia-reference projected eclipse offset -0.008864 d (photometric period projection allowance 0.000993 d). The approximate central duration 4.03 h vs median local-model width 3.20 h is only an approximate comparison; this

radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated eclipses persist in S1,37,98. Aperture depth changes from about210 to248 ppt; pooled parity depths confound sector coverage and do not establish stable unequal eclipse kinds. Gaia period matches the measured spacing. Intrinsic depth requires dilution modeling.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 317800184: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 18 distinct eclipse events in selected sectors [6, 87, 98]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [1, 2, 3, 4, 595, 596, 597, 598, 599, 600, 601, 685, 688, 689, 692, 693, 696, 697]; excluded cycles [] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 18 retained reference-eclipse midtimes give P=3.6897809447 +/-0.0000051256 d, observed reference eclipse epoch BTJD 1475.6552350. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S33 deficit peak [8, 7] vs target pixel [8, 7]; deficit-target separation 1.572 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.114. Capable neighbours: Gaia 2992486788106386560: 5.80 arcsec, G 12.206, required fractional eclipse 0.143, pixel fractional loss 0.031893555945530914
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 31.894/33.228/32.967 ppt, with 7 stacked events. QLP retained-reference fitted median 50.474 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 2992486788106386688, P=3.6896677330+/-0.0001218264 d, e=0.023021, omega=7.7054 deg. Closest edge-on conjunction offset 0.055950 d (0.015164 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.048574 d at the measured epoch. Near-Gaia-reference projected eclipse offset 0.022552 d (photometric period projection allowance 0.001512 d). The approximate central duration 3.92 h vs

median local-model width 2.36 h is only an approximate comparison; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated eclipses span S6,87,98 with sector-dependent depths around45-62 ppt. This limits precision but does not erase the localized repeat pattern.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 219033622: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors [15, 23]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [0, 2, 31]; excluded cycles [32] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 retained reference-eclipse midtimes give P=6.9464765822 +/-0.0004245408 d, observed reference eclipse epoch BTJD 1713.8087063. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S16 deficit peak [7, 7] vs target pixel [7, 7]; deficit-target separation 2.063 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.101. Capable neighbours: None within 60 arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 127.885/127.103/125.218 ppt, with 4 stacked events. QLP retained-reference fitted median 132.326 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 1558979055781011712, P=6.9468940696+/-0.0004207749 d, e=0.016919, omega=104.5859 deg. Closest edge-on conjunction offset -0.043887 d (-0.006317 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.093470 d at the measured epoch. Near-Gaia-reference projected eclipse offset 0.035853 d (photometric period projection allowance 0.081087 d). The approximate central duration 6.09 h vs median local-model width 3.02 h is only an approximate comparison; this

radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Three constrained same-kind events in S15 and S23 determine the ephemeris; S23 cycle32 is retained as a raw repeat but excluded from timing because sparse sampling leaves its egress poorly constrained. S76 did not supply a usable selected event window and is not a clean non-detection. The independent S16 cutout contains four repeating deep target-centered deficits. The timing baseline is shorter than the available sector list suggests.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R214. TIC 312725755

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 312725755: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section 2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors [19, 45, 73]. The lead inspected representative raw-event plots and numeric fit output; the helper independently audited timing and pixel exceptions. All fitted windows are preserved. Timing includes historical cycles [0, 1, 63, 64, 130]; excluded cycles [] remain in the raw evidence. Fits with midpoint covariance uncertainty larger than the seeded eclipse duration are excluded as unconstrained, not treated as timing measurements. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 retained reference-eclipse midtimes give P=11.3049942194 +/-0.0000343148 d, observed reference eclipse epoch BTJD 1823.1102837. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using quadrature-free conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage.
3. **Target attribution: pass at TESS image resolution.** Historical S19 deficit peak [7, 7] vs target pixel [7, 7]; deficit-target separation 4.360 arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual 0.563. Capable neighbours: Gaia 3451087895436075136: 38.86 arcsec, G 14.703, required fractional eclipse 0.813, pixel fractional loss 0.00961169700126623
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths 43.459/44.495/41.201 ppt, with 2 stacked events. QLP retained-reference fitted median 47.711 ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3 3451087861074378752, P=11.3048869586+/-0.0034114104 d, e=0.136183, omega=311.3174 deg. Closest edge-on conjunction offset 0.134039 d (0.011857 phase), full-SB1-covariance linear propagated Gaia uncertainty 0.514953 d at the measured epoch. Near-Gaia-reference projected eclipse offset 0.120417 d (photometric period projection allowance 0.004358 d). The approximate central duration 11.87 h vs median local-model width 8.50 h is only an approximate comparison; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Five fitted repeating eclipses span S19,45,73. The measured widths are long but compatible with approximate Gaia/TIC geometry; intrinsic depths and stellar parameters need detailed modeling.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

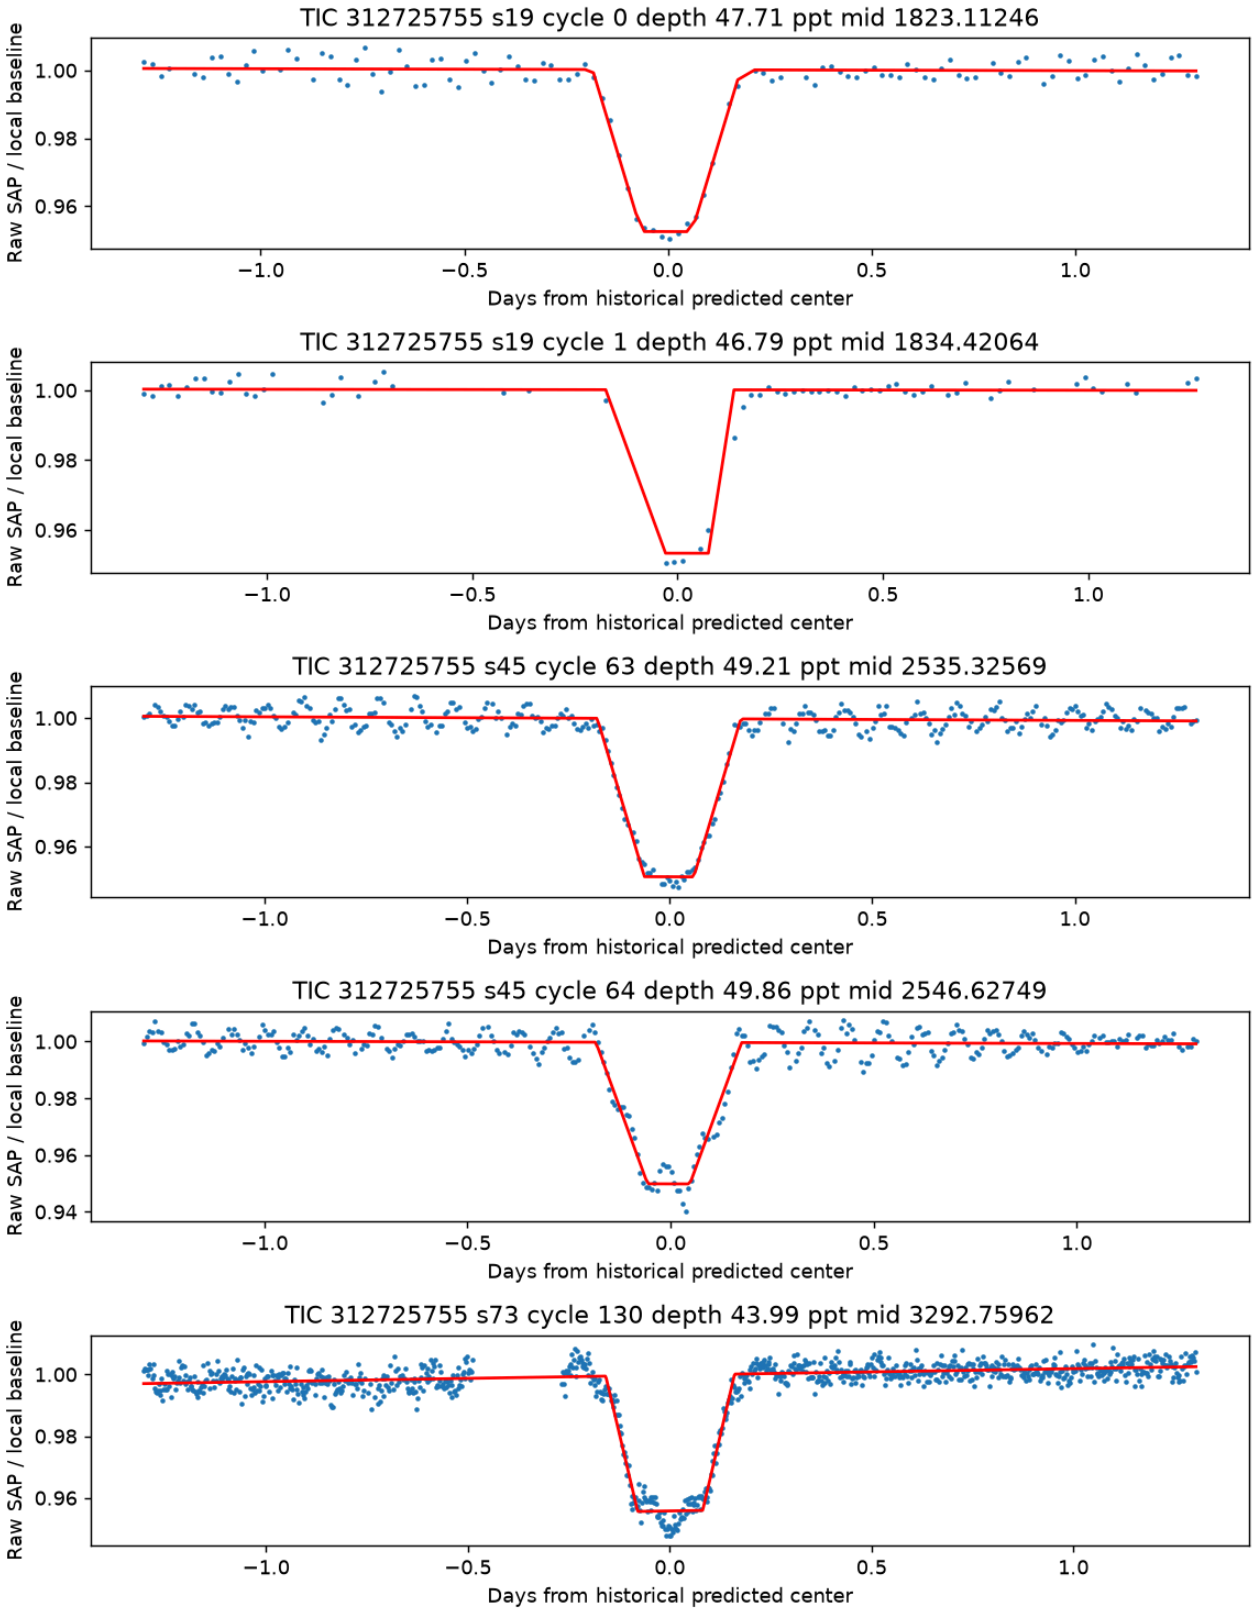
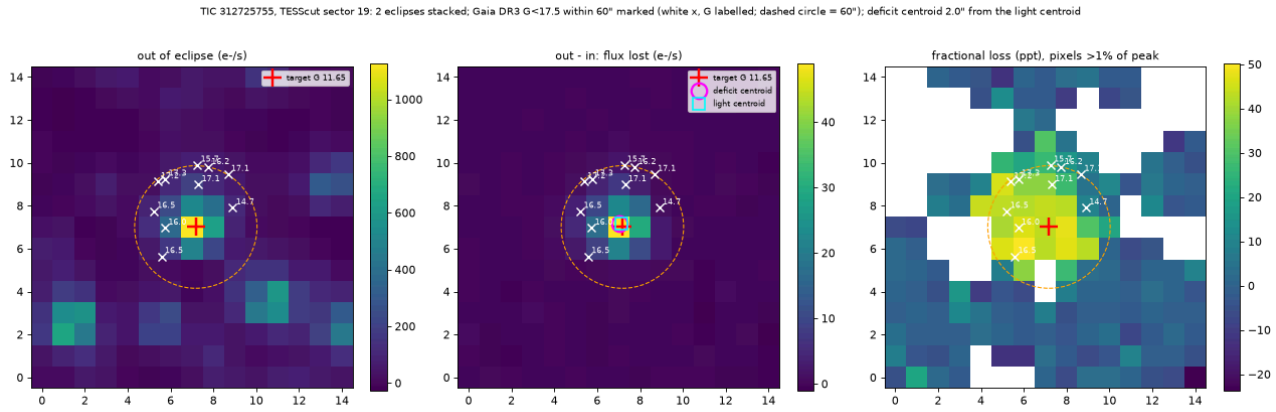
Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R214. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R214; raw-events.png. Representative raw-flux eclipse windows; fitted timing and quality qualifications are in the report.



R214; diff_s19.png. Archived target-pixel eclipse-deficit evidence; capable-neighbour and resolution limitations remain as stated.

Spectroscopic-orbit period folds: near-TESS-orbital-period evidence

R215. TIC 167178300

physical_verdict: PROBABLE

novelty_status: no prior EB identified in seven scoped groups; cachedChopardv1.2.0 exact IDs no overlap; laterreleases/embargo93 unknown

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry or multi-source PRF localization

Archived source: sanitized report text.

> Supervisor-accepted physical review: PROBABLE. Included under the paper's stated physical tier and bounded catalogue scope. Earlier pending-admission wording below records the original handoff.

TIC 167178300: PROBABLE

Scientific method/population: Gaia period fold / 12-14.8d selection-gap recovery. Physical review completion: complete bounded first pass, independently audited in helper/AUDIT.md; supervisor admission pending. The band pilot tests underreviewed/threshold-selected outcomes; the original SB1 fold already searched this period range, so these are not recoveries from an SB1 veto. Catalogue novelty is separate: no prior EB identified in seven scoped groups; cachedChopardv1.2.0 exact IDs no overlap; laterreleases/embargo93 unknown.

1. Repeated raw eclipses: PASS. 3 fit-eligible raw SAP events in sectors [33, 72]. Trapezoid depths median 70.54 ppt; duration median 8.58 h. All saved events, rejected fits and raw files are identified in timing-results.json; no claim that other sectors are clean nulls. QUALITY==0 used. Existing raw observations were remeasured, not merely called eclipses from BLS.
2. Eclipse timing: PASS. P=12.2156676717 d; A-eclipse reference epoch BTJD 1479.05938216; OLS scatter SE 2.52451973e-05 d; residual RMS 1.465 min. This reference epoch is extrapolated from the fitted sector33/72 timings, not a directly fitted eclipse at BTJD1479. This SE excludes cadence/template/extraction systematics and is not calibrated coverage. Fits are representative, not all-event precision ephemerides.
3. Target pixels: UNCERTAIN. Sector 33, 2 event stack, peak pixel [7, 8] equals target [7, 8]; centroid-target 3.84 arcsec. 6 distinct Gaia neighbours could supply the flux under the conservative total-flux bound. Close neighbours prevent an unqualified target identification; nearest-target centroid supports but does not settle it. Catalogue incompleteness/unresolved companions are not excluded. Gaia position used consistently with target ID. The older diffstack n_possible field includes the target itself; this report explicitly removes it.
4. Alternative reduction: PASS as a processing check. Own TESScut extraction using median faint-pixel background and target 3x3 aperture reproduces deficit 36.09 ppt. The difference-stack receipt records per-event aperture depths. These are the same TESS photons, not an independent observing occasion; dilution/apertures explain differing QLP depths.
5. Gaia geometry: PASS for consistency, not a precision solution. Eclipse P differs from Gaia by 0.537 quoted Gaia period errors. A-conjunction epoch difference 0.450 propagated marginal-error sigma. Gaia mass function 0.1642 solar masses, minimum companion mass 0.893 solar masses for TIC primary mass 1.190. TIC R1=3.225 solar radii. Illustrative edge-on R2=1solar-radius duration at this

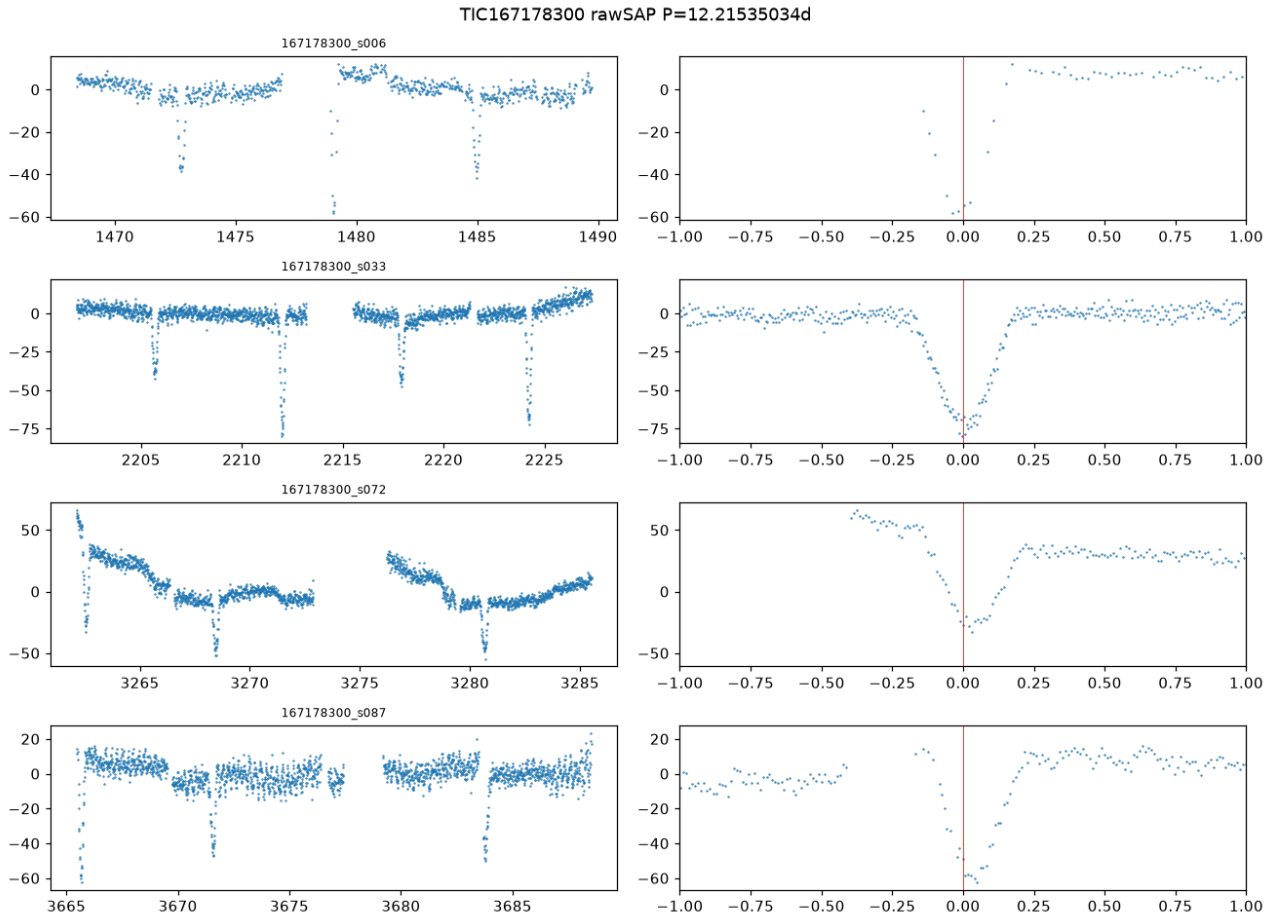
conjunction 12.02 h, longer than observed; impact/inclination can shorten it. This is an existence/consistency check, not a fitted mass-radius claim. Correlated Gaia errors were not modeled; no arbitrary sigma veto.

Seven catalogue groups: fresh VSX60arcsec, ASAS-SN60arcsec, SIMBAD exactGaiaDR3, Gaia vari_eclipsing_binary exactID, Prsa2022 5arcsec, IJspeert2024 5arcsec, vetted Kostov2025 tables3+4 5arcsec all returned successful receipts. No on-target EB match in this bounded scope. Any VSX/ASAS-SN neighbour is retained as attribution evidence, not mistaken for target identity. Full rows, UTC queries and response hashes are in catalogue coverage. The latter two Kostov tables form one group. No external messaging or public/paper edits.

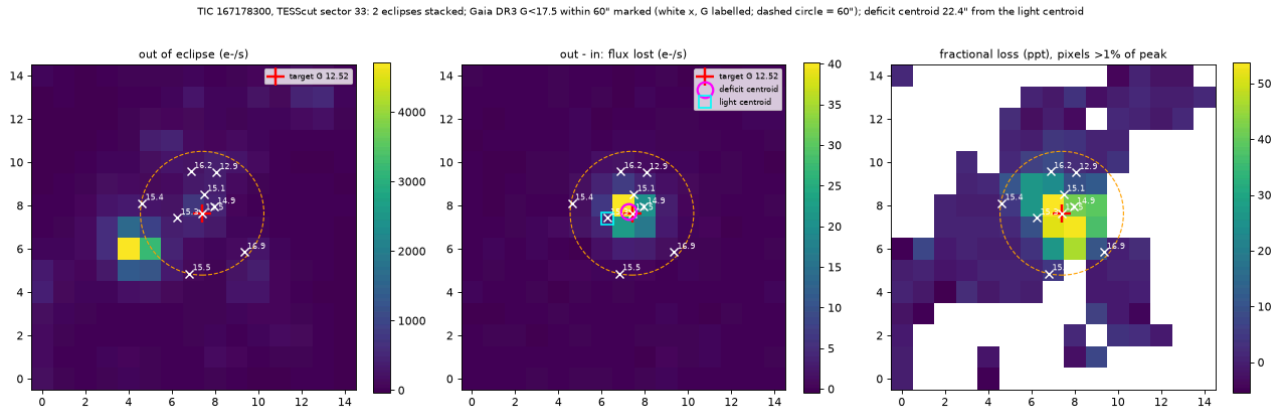
Limitations: Capable Gaia neighbours remain at 58.583arcsec, 41.62arcsec, 12.984arcsec, 24.468arcsec, 18.174arcsec, 59.428arcsec. Deficit centroid favors target, but close blend is unresolved without a PRF/deblend uncertainty test. Next check: Pixel/PRF assessment against capable neighbours before any confirmed admission; supervisor review.

Lead audit: scripts inspected and deciding numeric outputs reconciled with raw SAP plots, full Gaia NSS metadata, source IDs and real TESScut pixels. Apparent failure/non-detection is not called physical refutation unless contrary evidence is present. Independent helper audit uncertainty caveats are retained. The helper verified deciding artifacts, not an exhaustive literature search.

Accepted review key: R215. Pilot selection and limitations, independent audit, and catalogue receipts. Nearby files contain the deciding pixel measurements and hashes. This public archive omits raw FITS and sanitizes local paths; scripts are archival rather than turnkey.



R215; band-167178300.png. Exploratory selection and photometric evidence; selection and period qualifications remain as stated.



R215; diff_pilot.png. Target-pixel deficit evidence; the near-orbital-period cases remain probable because capable close neighbours are unresolved.

R216. TIC 325573958

physical_verdict: PROBABLE

1. Repeated raw eclipses: PASS. 4 fit-eligible raw SAP events in sectors [54, 81]. Trapezoid depths median 202.25 ppt; duration median 7.16 h. All saved events, rejected fits and raw files are identified in timing-results.json; no claim that other sectors are clean nulls. QUALITY==0 used. Existing raw observations were remeasured, not merely called eclipses from BLS.
2. Eclipse timing: PASS. P=13.0817227307 d; A-eclipse reference epoch BTJD 2772.49069574; OLS scatter SE 1.39974276e-05 d; residual RMS 0.813 min. This SE excludes cadence/template/extraction systematics and is not calibrated coverage. Fits are representative, not all-event precision ephemerides.
3. Target pixels: UNCERTAIN. Sector 81, 2 event stack, peak pixel [7, 7] equals target [7, 7]; centroid-target 2.52 arcsec. 3 distinct Gaia neighbours could supply the flux under the conservative total-flux bound. Close neighbours prevent an unqualified target identification; nearest-target centroid supports but does not settle it. Catalogue incompleteness/unresolved companions are not excluded. Gaia position used consistently with target ID. The older diffstack n_possible field includes the target itself; this report explicitly removes it.
4. Alternative reduction: PASS as a processing check. Own TESScut extraction using median faint-pixel background and target 3x3 aperture reproduces deficit 107.57 ppt. The difference-stack receipt records per-event aperture depths. These are the same TESS photons, not an independent observing occasion; dilution/apertures explain differing QLP depths.
5. Gaia geometry: PASS for consistency, not a precision solution. Eclipse P differs from Gaia by 1.597 quoted Gaia period errors. A-conjunction epoch difference 1.565 propagated marginal-error sigma. Gaia mass function 0.2329 solar masses, minimum companion mass 1.022 solar masses for TIC primary mass 1.120. TIC R1=3.535 solar radii. Illustrative edge-on R2=1solar-radius duration at this conjunction 8.17 h, longer than observed; impact/inclination can shorten it. This is an

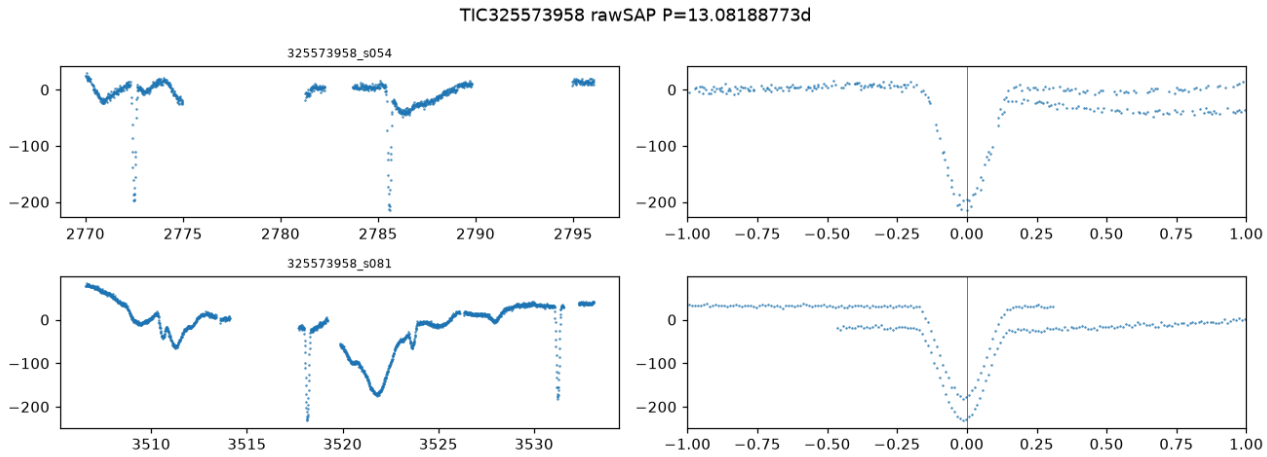
existence/consistency check, not a fitted mass-radius claim. Correlated Gaia errors were not modeled; no arbitrary sigma veto.

Seven catalogue groups: fresh VSX60arcsec, ASAS-SN60arcsec, SIMBAD exactGaiaDR3, Gaia vari_eclipsing_binary exactID, Prsa2022 5arcsec, IJspeert2024 5arcsec, vetted Kostov2025 tables3+4 5arcsec all returned successful receipts. No on-target EB match in this bounded scope. Any VSX/ASAS-SN neighbour is retained as attribution evidence, not mistaken for target identity. Full rows, UTC queries and response hashes are in catalogue coverage. The latter two Kostov tables form one group. No external messaging or public/paper edits.

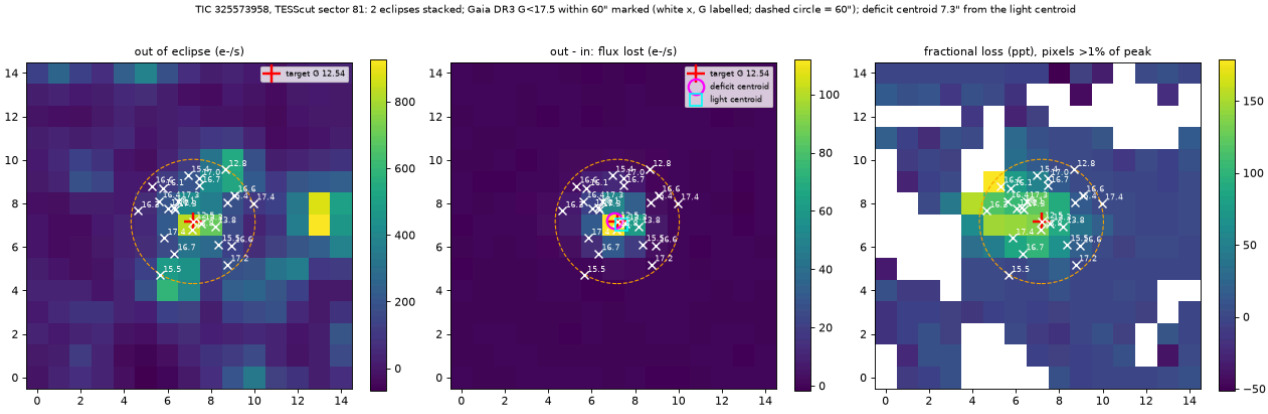
Limitations: Capable Gaia neighbours remain at 57.77arcsec, 7.958arcsec, 20.628arcsec. Deficit centroid favors target, but close blend is unresolved without a PRF/deblend uncertainty test. Next check: Pixel/PRF assessment against capable neighbours before any confirmed admission; supervisor review.

Lead audit: scripts inspected and deciding numeric outputs reconciled with raw SAP plots, full Gaia NSS metadata, source IDs and real TESScut pixels. Apparent failure/non-detection is not called physical refutation unless contrary evidence is present. Independent helper audit uncertainty caveats are retained. The helper verified deciding artifacts, not an exhaustive literature search.

Accepted review key: R216. Pilot selection and limitations, independent audit, and catalogue receipts. Nearby files contain the deciding pixel measurements and hashes. This public archive omits raw FITS and sanitizes local paths; scripts are archival rather than turnkey.



R216; band-325573958.png. Exploratory selection and photometric evidence; selection and period qualifications remain as stated.



R216; diff_pilot.png. Target-pixel deficit evidence; the near-orbital-period cases remain probable because capable close neighbours are unresolved.

Spectroscopic-orbit period folds: fixed G 11.5-12.5 comparison

Fixed magnitude comparison. Sixty remaining screened Gaia spectroscopic-orbit period-fold candidates were reviewed: 30 at G = 11.5-12 and 30 at G = 12-12.5, the latter split equally between historical chunks 6 and 7. The initial 120-target queue was seeded (2026103101) before review. Four inventory-magnitude boundary substitutions (seed 2026103102; two active and two reserved) occurred while the first processing group was being reviewed, solely by the magnitude rule. Original queues are retained. Historical inventory magnitudes differ slightly from Gaia DR3 values: later crosschecks showed the removed objects remained inside the DR3 intervals. All final 120 satisfy both definitions. This is a sample from boundary-valid historical screening strata, not a pristine random sample of all eligible DR3 stars. Both the first 60 and the reserved second 60 have now completed the bounded review, giving 60 selected targets in each magnitude interval. No reserved target was replaced after review. Scientific summaries use Gaia DR3 G, with inventory G preserved separately.

Physical confirmation among selected candidates. At G = 11.5-12 (actual DR3 range 11.6764-11.9742), 27/30 are physically confirmed (90.0%; descriptive Wilson 95% interval 74.4-96.5%), 3 probable and 0 plausible; 30 are new counted additions. At G = 12-12.5 (actual DR3 range 12.0029-12.4879), 21/30 are physically confirmed (70.0%; descriptive Wilson 95% interval 52.1-83.3%), 8 probable and 1 plausible; 28 are new counted additions. Every selected target remains in its denominator, including any unavailable or execution-incomplete outcome; all 60 completed the bounded review. TIC 377389892 is a confirmed known VSX EA recovery (0.02 arcsec counterpart), included in physical confirmation and excluded from new additions. Probable and plausible outcomes remain separate; plausible cases add nothing. These descriptive confirmation fractions concern remaining screened candidates, not blind discovery yield or completeness. Wilson intervals are binomial model summaries despite finite historical strata. Case mix, prior depletion of the bright stratum below G = 11.663, and selection bookkeeping prevent a causal magnitude interpretation.

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry / multi-source PRF localization

Archived source: sanitized report text.

TIC 428691463: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 15 distinct eclipse events in selected sectors[59, 86]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 15 same-kind midtimes give P=2.2025512596 ±0.0000032099d, reference eclipse epoch BTJD2912.7110288, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after check.** Historical S59 deficit peak[7, 7] vs target pixel[8, 7]; deficit-target separation3.708arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.815. Capable neighbours: Gaia 251403200552910592: 6.95 arcsec, G12.261, required fractional eclipse0.023, pixel fractional loss0.005518074279438695; Gaia 251403200553995008: 13.52 arcsec, G16.015, required fractional eclipse0.465, pixel fractional loss0.005042044222833572; Gaia 251403234912639616: 39.32 arcsec, G15.736, required fractional eclipse0.361, pixel fractional loss0.0023197334242561615
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths5.316/4.931/4.325ppt, with 10 stacked events. QLP selected-kind fitted median10.135ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3251403200552912128, P=2.2025752205±0.0000738127d, e=0.023863, omega=315.1974deg. Closest edge-on conjunction offset-0.031275d (-0.014199phase), full-SB1-covariance linear propagated Gaia uncertainty0.077205d at the measured epoch. Near-Gaia-reference projected eclipse offset-

0.003816d (photometric period projection allowance0.003679d). The approximate central duration3.88h vs observed median1.34h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unresolved attribution: capable neighbor Gaia251403200552910592 at6.95arcsec needs only2.3% fractional eclipse. Deficit centroid lies between target and neighbor; PSF residual0.815 and uncalibrated centroid cannot discriminate. Real repeated eclipses remain probable for this target.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 167105778: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[15, 75, 83]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=8.5865668060 ±0.0000273371d, reference eclipse epoch BTJD1718.8649126, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S56 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.804arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.490. Capable neighbours: Gaia 1968960312990727296: 10.12 arcsec, G14.833, required fractional eclipse0.441, pixel fractional loss0.02316814965491679; Gaia 1968960278623106176: 55.49 arcsec, G14.881, required fractional eclipse0.460, pixel fractional loss-0.001106644215653597
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths23.168/22.598/20.538ppt, with 4 stacked events. QLP selected-kind fitted median24.975ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3196896031299072588 8, P=8.5870099785±0.0010707120d, e=0.017110, omega=153.5675deg. Closest edge-on conjunction offset-0.155334d (-0.018089phase), full-SB1-covariance linear propagated Gaia uncertainty0.199645d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.086642d (photometric period projection allowance0.004237d). The approximate central

duration9.82h vs observed median6.95h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Capable G14.83 neighbor10.1arcsec away requires44% eclipse. Deficit is0.18pixel from target and0.47pixel from neighbor; image favors target, with uncalibrated centroid resolution retained as limitation.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 48212656: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 15 distinct eclipse events in selected sectors[36, 62, 89]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=9.0832698961 ±0.0000108660d, reference eclipse epoch BTJD2290.1567712, kind: Deeper primary (odd half-period cycles). Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S62 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation0.773arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.179. Capable neighbours: Gaia 5463218573976102400: 45.22 arcsec, G13.926, required fractional eclipse0.509, pixel fractional loss0.010378443232646176
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths48.360/47.433/42.752ppt, with 5 stacked events. QLP selected-kind fitted median73.015ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35463218604039665408, P=9.0837171230±0.0011010123d, e=0.012056, omega=249.6383deg. Closest edge-on conjunction offset-0.076515d (-0.008423phase), full-SB1-covariance linear propagated Gaia uncertainty0.253510d at the measured epoch. Near-Gaia-reference projected eclipse offset0.016955d (photometric period projection allowance0.002271d). The approximate central duration8.20h vs observed median5.58h permits noncentral geometry; this radius/minimum-mass estimate is not a

detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipses approximately40/73ppt establish doubled orbital period. Odd historical half-period cycles are deeper primaries and alone define ephemeris. Historical cutout mixes eclipse kinds.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
36	0	2285.6144732	0.003472	40.112	usable; same-kind selection applies

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 442662494: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[9, 37, 90]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=15.8202440581 ±0.0000267968d, reference eclipse epoch BTJD1555.0654980, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S36 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.803arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.968. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths279.938/261.135/234.930ppt, with 2 stacked events. QLP selected-kind fitted median317.962ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3525708361458224128, P=15.8200347806±0.0026074222d, e=0.103885, omega=111.0794deg. Closest edge-on conjunction offset0.003691d (0.000233phase), full-SB1-covariance linear propagated Gaia uncertainty0.256392d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.011796d (photometric period projection allowance0.001983d). The approximate central duration7.35h vs observed median5.41h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Historical PSF fit residual0.968 is poor, though target-centered deficit and no capable catalogued neighbor support attribution. Aperture/sector-dependent depths approximately277-331ppt; no intrinsic undiluted depth is inferred.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

TIC 280881615: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors[59, 86]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=5.2631068082 ±0.0000072351d, reference eclipse epoch BTJD2912.9426599, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S53 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation2.424arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.210. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths133.539/131.270/126.773ppt, with 5 stacked events. QLP selected-kind fitted median139.117ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3500313662204983936, P=5.2629890551±0.0002254657d, e=0.010989, omega=299.7018deg. Closest edge-on conjunction offset0.087594d (0.016643phase), full-SB1-covariance linear propagated Gaia uncertainty0.099605d at the measured epoch. Near-Gaia-reference projected eclipse offset0.031073d (photometric period projection allowance0.003473d). The approximate central duration5.07h vs observed median3.46h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Triangular ingress and egress repeat cleanly. No capable neighbor under the approximate G-band flux screen.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Archived source: sanitized report text.

TIC 238857132: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 21 distinct eclipse events in selected sectors[19, 59, 86]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=4.1681777841 ±0.0000043833d, reference eclipse epoch BTJD1819.0960960, kind: Deeper primary (even half-period cycles). Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S59 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation1.364arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.500. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths102.438/99.296/95.399ppt, with 12 stacked events. QLP selected-kind fitted median145.901ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3179205929877639680, P=4.1679867378±0.0002603474d, e=0.021003, omega=258.5500deg. Closest edge-on conjunction offset0.077346d (0.018557phase), full-SB1-covariance linear propagated Gaia uncertainty0.096978d at the measured epoch. Near-Gaia-reference projected eclipse offset0.011818d (photometric period projection allowance0.001503d). The approximate central duration7.74h vs observed median5.00h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipses approximately75/147ppt establish doubled orbital period. Even half-period cycles are deeper primaries and alone define ephemeris. Historical cutout mixes eclipse kinds.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

R223. TIC 60249512

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 60249512: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 10 distinct eclipse events in selected sectors[7, 61, 88]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=15.3007645492 ±0.0000224480d, reference eclipse epoch BTJD1497.6542271, kind: Selected conjunction, even half-period cycles; primary/secondary depth identity ambiguous. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S88 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.783arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.113. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths273.940/271.050/261.562ppt, with 4 stacked events. QLP selected-kind fitted median309.258ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3551236948821908774 4, P=15.2997416314±0.0023368048d, e=0.023463, omega=147.8744deg. Closest edge-on conjunction offset0.070489d (0.004607phase), full-SB1-covariance linear propagated Gaia uncertainty0.159401d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.003161d (photometric period projection allowance0.001616d). The approximate central duration10.68h vs observed median8.42h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Similar eclipse depths do not establish half orbital period. Consecutive sector88 spacings7.682814/7.617839/7.682757d alternate; same-kind spacings15.300653/15.300596d support full orbital period. Even half-period cycles define selected-conjunction epoch; deeper-primary identity is not claimed. Historical cutout mixes eclipse kinds.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 250562568: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[18, 85]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=4.8539745097 ±0.0000139746d, reference eclipse epoch BTJD1793.7829364, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S18 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.867arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.317. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths61.057/62.870/63.120ppt, with 4 stacked events. QLP selected-kind fitted median60.978ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3359013773655012096, P=4.8534475881±0.0003560668d, e=0.073594, omega=200.0311deg. Closest edge-on conjunction offset0.023951d (0.004935phase), full-SB1-covariance linear propagated Gaia uncertainty0.099201d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.128329d (photometric period projection allowance0.004039d). The approximate central duration7.63h vs observed median6.42h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated eclipse; alternative aperture supports target. Depth varies with aperture/dilution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

TIC 325787864: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 21 distinct eclipse events in selected sectors[65, 101]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 21 same-kind midtimes give P=1.9945846934 ±0.0000015903d, reference eclipse epoch BTJD3069.1499357, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S38 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.530arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.496. Capable neighbours: Gaia 5856732789162911104: 12.88 arcsec, G15.940, required fractional eclipse0.217, pixel fractional loss0.005861548844272418; Gaia 5856732789171468032: 14.25 arcsec, G16.231, required fractional eclipse0.281, pixel fractional loss0.004511681199667806; Gaia 5856735739766857984: 16.42 arcsec, G17.423, required fractional eclipse0.833, pixel fractional loss0.004408390932729964; Gaia 5856732784829357952: 18.94 arcsec, G15.771, required fractional eclipse0.186, pixel fractional loss0.005861548844272418; Gaia 5856732823522662912: 23.11 arcsec, G14.857, required fractional eclipse0.083, pixel fractional loss0.001221865944613266; Gaia 5856735744100421120: 28.93 arcsec, G16.951, required fractional eclipse0.541, pixel fractional loss0.004408390932729964; Gaia 5856732823522663808: 29.41 arcsec, G16.575, required fractional eclipse0.385, pixel fractional loss0.001221865944613266; Gaia 5856732754803167744: 29.83 arcsec, G14.363, required fractional eclipse0.055, pixel fractional loss0.004511681199667806; Gaia 5856732823501661056: 30.15 arcsec, G17.082, required fractional eclipse0.610, pixel fractional loss0.004054763655936261; Gaia 5856732823522662400: 33.07 arcsec, G16.742, required

4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths5.862/4.971/4.297ppt, with 12 stacked events. QLP selected-kind fitted median6.201ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3585673278482718745 6, P=1.9946207355±0.0002572320d, e=0.157853, omega=318.6257deg. Closest edge-on conjunction offset0.027840d (0.013958phase), full-SB1-covariance linear propagated Gaia uncertainty0.370918d at the measured epoch. Near-Gaia-reference projected eclipse offset0.076281d (photometric period projection allowance0.002137d). The approximate central duration4.15h vs observed median1.28h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Crowded field:29 capable neighbors include nearest12.9/14.3arcsec. Deficit0.17pixel from target and target-centered lost-light core favor target; no calibrated centroid uncertainty. Shallow morphology repeats in newer sectors; first-sector windows did not satisfy fitting coverage cuts and are not nulls.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 180871891: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors[29, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=13.0367888505 ±0.0000275594d, reference eclipse epoch BTJD2097.6610275, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S29 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation0.910arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.310. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths8.024/7.114/6.961ppt, with 2 stacked events. QLP selected-kind fitted median6.596ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3498809657429171488, P=13.0390915897±0.0016464671d, e=0.106260, omega=327.0889deg. Closest edge-on conjunction offset-0.327420d (-0.025111phase), full-SB1-covariance linear propagated Gaia uncertainty0.217962d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.025761d (photometric period projection allowance0.003610d). The approximate central duration6.79h vs observed median3.08h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four measured shallow eclipses across sectors29/104 establish repeatability and period. Target-centered deficit0.043pixel and no capable catalogued neighbor support attribution. Sector2 was downloaded but no event window passed coverage cuts; it is not a clean non-detection. No single-event availability gap remains.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 129565419: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[57, 84]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=8.9837069710 ±0.0000373305d, fitted ephemeris intercept at earliest retained cycle BTJD2860.2271612, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S56 deficit peak[14, 12] vs target pixel[7, 8]; deficit-target separation0.846arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.968. Capable neighbours: Gaia 1931241188635723264: 38.91 arcsec, G14.422, required fractional eclipse0.353, pixel fractional loss0.012421269831853259
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths25.891/25.695/23.795ppt, with 3 stacked events. QLP selected-kind fitted median30.212ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3193124118863572569 6, P=8.9845539995±0.0011354221d, e=0.046905, omega=323.0527deg. Closest edge-on conjunction offset-0.297531d (-0.033116phase), full-SB1-covariance linear propagated Gaia uncertainty0.325225d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.064598d (photometric period projection allowance0.010266d). The approximate central

duration6.22h vs observed median3.23h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Remote bright region dominates historical unrestricted peak and PSF residual0.968. Independent helper local5x5 re-stack residual0.115 and target centroid offset(-0.02,+0.01)pixel recover the target eclipse; three aperture depths24.40/23.92/22.14ppt support it. Capable neighbor38.91arcsec away lies1.90pixel from original deficit vs0.040pixel target.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 125690413: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 18 distinct eclipse events in selected sectors[15, 41, 55]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 18 same-kind midtimes give P=3.6868965634 ±0.0000323523d, fitted ephemeris intercept at earliest retained cycle BTJD1712.7815721, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S41 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation7.799arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.454. Capable neighbours: Gaia 1841055774590654720: 24.35 arcsec, G15.751, required fractional eclipse0.759, pixel fractional loss0.016480613631840144; Gaia 1841055770295761664: 42.81 arcsec, G15.802, required fractional eclipse0.795, pixel fractional loss0.004229247182978673; Gaia 1841055740230914688: 50.54 arcsec, G15.518, required fractional eclipse0.617, pixel fractional loss0.0027038765085001747
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths22.331/22.134/21.692ppt, with 7 stacked events. QLP selected-kind fitted median21.909ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3184105649614516 3776, P=3.6869823318±0.0002444206d, e=0.064161, omega=270.3731deg. Closest edge-on conjunction

offset-0.058793d (-0.015946phase), full-SB1-covariance linear propagated Gaia uncertainty0.075668d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.028002d (photometric period projection allowance0.011614d). The approximate central duration8.23h vs observed median4.44h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Structured sector41 baseline gives broad34ppt cycle196, residual -0.038d and reduced chi square5.25. Retained event and inflated covariance document this; clean22ppt repeats occur in sectors15/55. Capable neighbors are24.35arcsec or farther,1.55pixel or farther from deficit vs0.371pixel target. Timing errors are not total uncertainty.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Archived source: sanitized report text.

TIC 445045766: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors[60, 74]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=5.0364803869 ±0.0000125874d, fitted ephemeris intercept at earliest retained cycle BTJD2939.7678090, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S47 deficit peak[8, 8] vs target pixel[7, 8]; deficit-target separation3.908arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.781. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths23.308/23.874/22.969ppt, with 5 stacked events. QLP selected-kind fitted median25.792ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3104084811688657612 8, P=5.0364132762±0.0002075065d, e=0.017166, omega=36.3338deg. Closest edge-on conjunction offset0.083686d (0.016616phase), full-SB1-covariance linear propagated Gaia uncertainty0.104481d at the measured epoch. Near-Gaia-reference projected eclipse offset0.049728d (photometric period projection allowance0.006369d). The approximate central duration4.07h vs observed median1.94h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: No capable catalogued neighbor within60arcsec. Deficit0.186pixel from target; three alternative aperture depths23.3-23.9ppt agree.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 120037640: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[93, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=3.6982624070 ±0.0000073790d, fitted ephemeris intercept at earliest retained cycle BTJD3833.6806832, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S66 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.736arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.697. Capable neighbours: Gaia 6651016827935020032: 34.86 arcsec, G14.449, required fractional eclipse0.290, pixel fractional loss0.016812257550119572; Gaia 6651016961075479552: 52.29 arcsec, G13.179, required fractional eclipse0.106, pixel fractional loss0.004252985656066122
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths22.768/22.273/20.123ppt, with 6 stacked events. QLP selected-kind fitted median24.000ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR36651016862294758784, P=3.6985144102±0.0001310459d, e=0.061638, omega=94.3358deg. Closest edge-on conjunction offset-0.189153d (-0.051143phase), full-SB1-covariance linear propagated Gaia uncertainty0.110953d at the measured epoch. Near-Gaia-reference projected eclipse offset0.045461d (photometric period

projection allowance0.006870d). The approximate central duration6.02h vs observed median3.18h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Actual-epoch Gaia offset -0.189d (phase -0.051) exceeds historical phase screen; near Gaia reference projected offset is +0.045d. Gaia period uncertainty accumulates over baseline. Low eccentricity0.062 and recurrence agreement support association without arbitrary sigma veto. Capable neighbors are34.9arcsec or farther and1.72pixel or farther from deficit vs0.178pixel target.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 448485777: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[11, 99, 102]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=5.8952882395 ±0.0000227545d, fitted ephemeris intercept at earliest retained cycle BTJD1603.4712444, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after check.** Historical S11 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation5.303arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.300. Capable neighbours: Gaia 5847716106616806784: 14.44 arcsec, G15.332, required fractional eclipse0.976, pixel fractional loss0.0215936791346104; Gaia 5847716102285049344: 16.26 arcsec, G13.144, required fractional eclipse0.161, pixel fractional loss0.01979753444323785; Gaia 5847715728659680000: 20.52 arcsec, G14.358, required fractional eclipse0.419, pixel fractional loss0.03241426402958959; Gaia 5847715728659676800: 21.71 arcsec, G15.306, required fractional eclipse0.954, pixel fractional loss0.03276142993066764; Gaia 5847716102285056384: 25.76 arcsec, G15.235, required fractional eclipse0.896, pixel fractional loss0.0215936791346104; Gaia 5847716106616813440: 57.68 arcsec, G14.848, required fractional eclipse0.638, pixel fractional loss0.005557348234906238
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths33.268/29.822/29.128ppt, with 4 stacked events. QLP selected-kind fitted median37.981ppt. This separately extracted cutout is an alternative reduction of the same TESS

photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3584771572432743616O, P=5.8948949185±0.0003771119d, e=0.086403, omega=238.3671deg. Closest edge-on conjunction offset0.143279d (0.024306phase), full-SB1-covariance linear propagated Gaia uncertainty0.087194d at the measured epoch. Near-Gaia-reference projected eclipse offset0.062255d (photometric period projection allowance0.004687d). The approximate central duration11.63h vs observed median6.69h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Crowded field: G13.14 neighbor16.26arcsec away requires16.1% eclipse, deficit0.615pixel from neighbor vs0.252pixel target. Another14.44arcsec neighbor requires97.6%. Target is favored by central deficit and deeper1x1 aperture, but blending and uncalibrated localization leave attribution physically unresolved after completed checks.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
11	0	1603.4657715	0.010417	41.254	usable; same-kind selection applies

Archived source: sanitized report text.

TIC 158647370: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors[69, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=6.0132323218 ±0.0000060378d, fitted ephemeris intercept at earliest retained cycle BTJD3189.6585657, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S29 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.428arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.024. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths87.134/86.012/85.155ppt, with 5 stacked events. QLP selected-kind fitted median85.396ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3491632155903871948 8, P=6.0135821955±0.0002440543d, e=0.037327, omega=306.8532deg. Closest edge-on conjunction offset-0.114751d (-0.019082phase), full-SB1-covariance linear propagated Gaia uncertainty0.124315d at the measured epoch. Near-Gaia-reference projected eclipse offset0.048291d (photometric period projection allowance0.002814d). The approximate central duration5.66h vs observed median3.38h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: No capable catalogued neighbor. Approximately85-95ppt eclipses repeat; custom aperture depths85-87ppt agree.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Archived source: sanitized report text.

TIC 302190527: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[42, 57, 84]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=9.4703064823 ±0.0000113926d, fitted ephemeris intercept at earliest retained cycle BTJD2450.9782406, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S57 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation4.058arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.114. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths263.443/258.276/255.104ppt, with 3 stacked events. QLP selected-kind fitted median281.535ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR32779583640038802560, P=9.4713396104±0.0013422095d, e=0.105048, omega=22.4456deg. Closest edge-on conjunction offset-0.163176d (-0.017228phase), full-SB1-covariance linear propagated Gaia uncertainty0.259643d at the measured epoch. Near-Gaia-reference projected eclipse offset0.062045d (photometric period projection allowance0.002484d). The approximate central duration6.77h vs observed median5.09h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: No capable catalogued neighbor. Approximately275-283ppt raw eclipses repeat across widely separated sectors; alternative aperture depths255-263ppt are diluted extraction values.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 138941853: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[6, 32, 98]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=11.5985912130 ±0.0000160827d, fitted ephemeris intercept at earliest retained cycle BTJD1475.6404802, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S98 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation1.841arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.425. Capable neighbours: Gaia 3223511670208848896: 21.77 arcsec, G16.492, required fractional eclipse0.500, pixel fractional loss0.00821316823921336; Gaia 3223511734632170368: 33.94 arcsec, G16.100, required fractional eclipse0.351, pixel fractional loss0.005558516488320414; Gaia 3223511704568589952: 43.67 arcsec, G15.493, required fractional eclipse0.204, pixel fractional loss0.007256264006483505; Gaia 3223511429690683776: 44.80 arcsec, G13.282, required fractional eclipse0.033, pixel fractional loss0.0017700490677724006
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths9.200/8.300/6.809ppt, with 3 stacked events. QLP selected-kind fitted median9.255ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR33223511665912271232, P=11.6019567518±0.0050960393d, e=0.024700, omega=125.6521deg. Closest edge-on conjunction offset0.035580d (0.003067phase), full-SB1-covariance linear propagated Gaia uncertainty0.523683d at the measured epoch. Near-Gaia-reference projected eclipse offset0.351941d (photometric period projection allowance0.001512d). The approximate central duration7.90h vs observed median3.75h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Approximately8-10ppt eclipses repeat in sectors6/32/98. Deficit0.087pixel from target vs nearest capable source1.127pixel. Near-reference Gaia offset0.352d is descriptive; low-eccentricity orbit conjunction is poorly constrained. Actual epoch offset0.036d with0.524d propagated Gaia uncertainty is compatible.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 256665207: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 19 distinct eclipse events in selected sectors[58, 86]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 19 same-kind midtimes give P=2.7907385784 ±0.0000027067d, fitted ephemeris intercept at earliest retained cycle BTJD2884.6986301, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S55 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.481arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.177. Capable neighbours: Gaia 2238265718901540224: 32.78 arcsec, G16.300, required fractional eclipse0.384, pixel fractional loss0.005700579685187473; Gaia 2238265791919992576: 53.79 arcsec, G16.967, required fractional eclipse0.705, pixel fractional loss0.008951220717294421
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths7.140/6.683/6.612ppt, with 10 stacked events. QLP selected-kind fitted median6.603ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR32238265757560253312, P=2.7907557184±0.0000952841d, e=0.051842, omega=220.0501deg. Closest edge-on conjunction offset-0.023180d (-0.008306phase), full-SB1-covariance linear propagated Gaia uncertainty0.096919d at the measured epoch. Near-Gaia-reference projected eclipse offset-

0.007857d (photometric period projection allowance0.002420d). The approximate central duration4.78h vs observed median1.41h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Approximately6-7ppt flat-bottom eclipses repeat. No compelling even/odd split establishes half/double alias; full Gaia period agrees with recurrence. Nearest capable source32.78arcsec away,1.70pixel from deficit vs0.166pixel target.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 91628894: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors[10, 64, 100]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=6.7661193197 ±0.0000092506d, fitted ephemeris intercept at earliest retained cycle BTJD1576.8187199, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S63 deficit peak[7, 7] vs target pixel[7, 8]; deficit-target separation7.925arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.290. Capable neighbours: Gaia 5348295453990085888: 19.20 arcsec, G15.582, required fractional eclipse0.381, pixel fractional loss0.01023010947109879; Gaia 5348295140443337472: 34.87 arcsec, G16.515, required fractional eclipse0.885, pixel fractional loss0.011668267374688467; Gaia 5348295453990088064: 37.41 arcsec, G16.480, required fractional eclipse0.857, pixel fractional loss0.011393153500120334; Gaia 5348295350910866688: 42.05 arcsec, G15.208, required fractional eclipse0.273, pixel fractional loss0.007769923584894719; Gaia 5348295350905264640: 43.46 arcsec, G16.548, required fractional eclipse0.912, pixel fractional loss0.007769923584894719; Gaia 5348295350910866176: 48.35 arcsec, G15.901, required fractional eclipse0.507, pixel fractional loss0.007769923584894719; Gaia 5348295282191399936: 56.55 arcsec, G16.151, required fractional eclipse0.636, pixel fractional loss0.0010946274488744217; Gaia 5348295144752436864: 58.14 arcsec, G16.385, required fractional eclipse0.786, pixel fractional loss0.004377720591664356

4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths9.974/10.396/9.922ppt, with 4 stacked events. QLP selected-kind fitted median10.761ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3534829544968081920 0, P=6.7670124687±0.0024326020d, e=0.198278, omega=64.3659deg. Closest edge-on conjunction offset-0.195924d (-0.028953phase), full-SB1-covariance linear propagated Gaia uncertainty0.279206d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.038730d (photometric period projection allowance0.001628d). The approximate central duration8.09h vs observed median7.38h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deficit0.377pixel from target; light-centroid shift1.05arcsec is a different quantity. Nearest capable source19.20arcsec away requires38.1% eclipse and lies0.675pixel from deficit. Central lost-light peak and consistent10ppt aperture depths favor target; no calibrated subpixel uncertainty is inferred.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 252737077: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors[16, 57, 84]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=10.2034445887 Ãƒâ€šÃ‚±0.0000145011d, reference eclipse epoch BTJD1757.7979046, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S57 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation4.251arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.943. Capable neighbours: Gaia 1995327181638998016: 42.69 arcsec, G12.539, required fractional eclipse0.653, pixel fractional loss0.013331207987805165; Gaia 1995327525236380800: 53.79 arcsec, G9.660, required fractional eclipse0.237, pixel fractional loss0.00028959663111898507
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths160.420/95.526/43.208ppt, with 3 stacked events. QLP selected-kind fitted median208.935ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR31995327254658341888, P=10.2047428233Ãƒâ€šÃ‚±0.0012404385d, e=0.066845, omega=343.3919deg. Closest edge-on conjunction offset-0.047365d (-0.004641phase), full-SB1-covariance linear propagated Gaia uncertainty0.203135d at the measured epoch. Near-Gaia-reference projected eclipse offset0.126599d (photometric period projection allowance0.001943d). The approximate central duration6.54h vs

observed median5.46h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Strong aperture dilution: raw QLP approximately209ppt versus cutout1/3/5 aperture160/96/43ppt. Deficit core is target-centered; capable neighbors42.7/53.8arcsec away are2.06/2.72pixels from the deficit centroid versus0.20pixel for target; blended local loss is not an intrinsic-source eclipse constraint. Poor total-light PSF residual0.943 reflects crowding; no intrinsic depth is inferred.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 369118947: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 9 distinct eclipse events in selected sectors[12, 93, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 9 same-kind midtimes give P=5.3592734775 Ãƒâ€šÃ‚±0.0000136631d, reference eclipse epoch BTJD1632.7557204, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S39 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.683arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.923. Capable neighbours: Gaia 5949510916010450048: 53.79 arcsec, G12.654, required fractional eclipse0.622, pixel fractional loss0.0011707993086129812
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths169.328/127.739/59.283ppt, with 4 stacked events. QLP selected-kind fitted median186.853ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35949512427837846144, P=5.3589663376Ãƒâ€šÃ‚±0.0003517770d, e=0.023477, omega=279.2669deg. Closest edge-on conjunction offset0.104460d (0.019493phase), full-SB1-covariance linear propagated Gaia uncertainty0.058542d at the measured epoch. Near-Gaia-reference projected eclipse offset0.033204d (photometric period projection allowance0.003170d). The approximate central duration6.24h vs observed median4.73h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Target-centered deficit despite poor0.923 total-light PSF residual in crowded field. Capable neighbor53.8arcsec away is well separated. Aperture-dependent diluted depth retained.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
12	0	1632.7355450	0.010417	186.853	usable; same-kind selection applies

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 399238907: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[80]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=4.1443054573 Ãƒâ€šÃ‚±0.0002790706d, reference eclipse epoch BTJD3480.3126460, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S80 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.732arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.329. Capable neighbours: Gaia 4468583068251428736: 16.59 arcsec, G14.439, required fractional eclipse0.537, pixel fractional loss0.03270235223204699; Gaia 4468582965172213888: 22.12 arcsec, G13.831, required fractional eclipse0.324, pixel fractional loss0.016929322145052952; Gaia 4468582969467512192: 23.01 arcsec, G14.622, required fractional eclipse0.628, pixel fractional loss0.016929322145052952; Gaia 4468583106906461184: 52.56 arcsec, G14.077, required fractional eclipse0.396, pixel fractional loss0.010143271811782536
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths34.251/31.049/29.498ppt, with 5 stacked events. QLP selected-kind fitted median42.314ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR34468583068251428864, P=4.1442204144Ãƒâ€šÃ‚±0.0002752424d, e=0.053485, omega=202.9714deg. Closest edge-on conjunction offset0.076594d (0.018482phase), full-SB1-covariance linear propagated Gaia uncertainty0.214766d at the measured epoch. Near-Gaia-reference projected eclipse offset0.013152d (photometric period projection allowance0.208187d). The approximate central duration9.18h vs observed median7.03h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Only QLP sector80 is available in the shared availability receipt, containing five measured repeats. Queue4.14670d is the historical screening seed, not current Gaia period; full NSS4.144220414d agrees measured period. Sector80 pipeline timing offsets are an uncalibrated systematic. Four capable neighbors are offset from the target-centered lost-light core; closest16.6arcsec.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 146319847: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[9, 63, 100]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=8.8705576715 Ãƒâ€šÃ‚±0.0000110757d, reference eclipse epoch BTJD1548.3578550, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S63 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation2.042arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.927. Capable neighbours: Gaia 5392222730215912320: 33.84 arcsec, G9.668, required fractional eclipse0.139, pixel fractional loss0.0016831041794920934
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths107.695/54.423/20.351ppt, with 3 stacked events. QLP selected-kind fitted median133.766ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3539221980963815091 2, P=8.8705042457Ãƒâ€šÃ‚±0.0005204978d, e=0.018718, omega=121.6281deg. Closest edge-on conjunction offset-0.008879d (-0.001001phase), full-SB1-covariance linear propagated Gaia uncertainty0.078702d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.015877d (photometric period projection allowance0.001451d). The approximate central duration6.01h vs observed median4.02h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Capable neighbor33.8arcsec away is distinct from the target-centered deficit. Raw depths105-138ppt and cutout apertures108/54/20ppt reflect substantial dilution; total-light PSF residual0.927 is poor and not used as a sole attribution test.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 466690912: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 32 distinct eclipse events in selected sectors[27, 94, 103]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 32 same-kind midtimes give P=2.1159658358 Ãƒâ€šÃ‚±0.0000011526d, reference eclipse epoch BTJD2037.8376563, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S66 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation6.475arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.677. Capable neighbours: Gaia 6366373024352389504: 49.13 arcsec, G15.303, required fractional eclipse0.883, pixel fractional loss0.011787977275723208
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths31.335/31.036/29.192ppt, with 12 stacked events. QLP selected-kind fitted median29.016ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3636637305871213043 2, P=2.1159665560Ãƒâ€šÃ‚±0.0000929679d, e=0.040428, omega=2.4544deg. Closest edge-on conjunction offset0.022977d (0.010859phase), full-SB1-covariance linear propagated Gaia uncertainty0.073318d at the measured epoch. Near-Gaia-reference projected eclipse offset0.023538d (photometric period projection allowance0.000898d). The approximate central

duration5.24h vs observed median5.25h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated flat-bottom eclipses with changing raw sector depths19-35ppt; aperture and baseline dependence is retained. Capable neighbor49.1arcsec away is distinct from the deficit core. Observed duration5.25h agrees approximate central estimate5.24h to the precision of its assumptions.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

TIC 436092743: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[55, 82]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=13.1290724046 Ãƒâ€šÃ‚±0.0000461943d, reference eclipse epoch BTJD2799.7762801, kind: Deeper primary (odd half-period cycles). Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S55 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.240arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.238. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths118.232/111.779/104.775ppt, with 4 stacked events. QLP selected-kind fitted median152.348ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3186033103376599488O, P=13.1281268605Ãƒâ€šÃ‚±0.0022765186d, e=0.011420, omega=39.9211deg. Closest edge-on conjunction offset0.178987d (0.013634phase), full-SB1-covariance linear propagated Gaia uncertainty0.443548d at the measured epoch. Near-Gaia-reference projected eclipse offset0.005007d (photometric period projection allowance0.008500d). The approximate central duration17.53h vs observed median13.88h permits noncentral geometry; this radius/minimum-

mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipses approximately153/100ppt establish full orbital period13.12907d, twice historical SAP branch. Odd half-period cycles are deeper primary eclipses and alone define ephemeris. Historical cutout stack mixes eclipse kinds; no capable neighbor.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[27, 68, 96]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=8.4145931953 Ãƒâ€šÃ‚±0.0000081269d, reference eclipse epoch BTJD2042.7168402, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S27 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation1.214arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.190. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths31.055/30.538/29.006ppt, with 3 stacked events. QLP selected-kind fitted median30.158ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR34702435241420083712, P=8.4129097571Ãƒâ€šÃ‚±0.0020308000d, e=0.169799, omega=71.4874deg. Closest edge-on conjunction offset-0.092244d (-0.010965phase), full-SB1-covariance linear propagated Gaia uncertainty0.475998d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.423882d (photometric period projection allowance0.001601d). The approximate central duration3.97h vs observed median3.76h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Eight measured repeats across three sectors. No capable catalogued neighbor; target-centered deficit. Raw depth26-31ppt varies by extraction/sector.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 140281693: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 15 distinct eclipse events in selected sectors[5, 33, 98]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 15 same-kind midtimes give P=3.8719820163 Ãƒâ€šÃ‚±0.0000030426d, reference eclipse epoch BTJD1440.1160470, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S32 deficit peak[8, 8] vs target pixel[8, 7]; deficit-target separation2.132arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual1.000. Capable neighbours: Gaia 2903798530942872704: 37.49 arcsec, G14.214, required fractional eclipse0.428, pixel fractional loss0.0062627425786385355; Gaia 2903798634022085504: 56.76 arcsec, G14.826, required fractional eclipse0.720, pixel fractional loss0.008418660852396504
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths40.235/37.239/29.706ppt, with 7 stacked events. QLP selected-kind fitted median42.031ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR32903798565302609536, P=3.8720833801Ãƒâ€šÃ‚±0.0002902097d, e=0.100248, omega=219.1844deg. Closest edge-on conjunction offset-0.037247d (-0.009619phase), full-SB1-covariance linear propagated Gaia uncertainty0.069345d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.009778d (photometric period projection allowance0.000825d). The approximate central

duration4.57h vs observed median3.89h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Target-centered deficit despite poor0.9999 total-light PSF residual caused by unrelated bright light outside target core. Capable neighbors37.5/56.8arcsec are spatially separate. Raw depth34-45ppt depends on sector aperture.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry / multi-source PRF localization

Archived source: sanitized report text.

TIC 128460489: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[7, 34, 88]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=6.3628732011 Ãƒâ€šÃ‚±0.0000073187d, reference eclipse epoch BTJD1493.6722577, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after check.** Historical S7 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation5.679arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.317. Capable neighbours: Gaia 5600259057572857856: 11.02 arcsec, G14.307, required fractional eclipse0.254, pixel fractional loss0.020584271802751925; Gaia 5600259091932595584: 37.61 arcsec, G13.736, required fractional eclipse0.160, pixel fractional loss0.00852574510837417; Gaia 5600258988853381376: 41.92 arcsec, G13.394, required fractional eclipse0.123, pixel fractional loss0.002302554160844853; Gaia 5600258885774167040: 59.41 arcsec, G15.688, required fractional eclipse0.845, pixel fractional loss0.007786925055711405
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths20.584/19.674/17.212ppt, with 4 stacked events. QLP selected-kind fitted median26.324ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35600259057572857984, P=6.3633869971Ãƒâ€šÃ‚±0.0004569123d, e=0.017282, omega=333.8953deg. Closest edge-on

conjunction offset-0.069923d (-0.010988phase), full-SB1-covariance linear propagated Gaia uncertainty0.086227d at the measured epoch. Near-Gaia-reference projected eclipse offset0.019477d (photometric period projection allowance0.001273d). The approximate central duration8.56h vs observed median3.68h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unresolved attribution after completed check: capable Gaia5600259057572857856 neighbor11.02arcsec away requires25.4percent intrinsic eclipse and shares rounded TESS pixel with target. Deficit centroid is0.270pixel from target and0.516pixel from neighbor, favoring target but without calibrated uncertainty sufficient to exclude neighbor. Local blended pixel loss cannot exclude that neighbor. Retain probable for target pending resolved photometry or multi-source PRF localization.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths5.337/4.380/3.702ppt, with 6 stacked events. Historical outputs are retained as measured pipeline evidence. QLP selected-kind fitted median8.985ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3186148844586100825 6, P=4.4421085480±0.0015018636d, e=0.092033, omega=131.7871deg. Closest edge-on conjunction offset0.070473d (0.015865phase), full-SB1-covariance linear propagated Gaia uncertainty0.342971d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.150613d (photometric period projection allowance0.005722d). The approximate central duration11.53h vs observed median9.76h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Crowded field with capable bright neighbor at11.93arcsec requiring only2.1% eclipse; target-centered deficit favors target but uncalibrated localization cannot securely distinguish close blended contributors. Attribution remains uncertain.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 362822264: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 2 distinct eclipse events in selected sectors[100, 103]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass with disclosed cycle assumptions.** 2 same-kind midtimes give P=18.1224025318 ±0.0004427023d, reference eclipse epoch BTJD4088.4759074, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S39 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation4.079arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.876. Capable neighbours: Gaia 5809488458121122688: 25.90 arcsec, G16.725, required fractional eclipse0.916, pixel fractional loss0.006363474205114983; Gaia 5809488458121125376: 27.52 arcsec, G14.468, required fractional eclipse0.129, pixel fractional loss0.006363474205114983; Gaia 5809489179675649024: 35.87 arcsec, G14.902, required fractional eclipse0.184, pixel fractional loss0.0015995434889155829; Gaia 5809489076596420224: 36.21 arcsec, G15.634, required fractional eclipse0.346, pixel fractional loss0.009451136465246602; Gaia 5809488458121137920: 38.81 arcsec, G14.778, required fractional eclipse0.166, pixel fractional loss0.007186929794530505; Gaia 5809489179675647104: 40.29 arcsec, G14.576, required fractional eclipse0.141, pixel fractional loss0.004786218431079745; Gaia 5809489076596419584: 42.94 arcsec, G16.597, required fractional eclipse0.816, pixel fractional loss0.000594145698815468; Gaia 5809488458121120128: 44.18 arcsec, G15.916, required fractional eclipse0.444, pixel fractional loss-0.00032071891081499976; Gaia 5809489076596420992: 48.38 arcsec, G16.615, required fractional

eclipse0.830, pixel fractional loss0.000594145698815468; Gaia 5809488458121518336: 50.76 arcsec, G16.488, required fractional eclipse0.740, pixel fractional loss-0.00032071891081499976; Gaia 5809489214035390848: 56.68 arcsec, G13.380, required fractional eclipse0.058, pixel fractional loss0.0001064147781249135; Gaia 5809489209723092096: 58.25 arcsec, G12.624, required fractional eclipse0.037, pixel fractional loss0.0013891626777344018

4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths17.021/13.194/6.730ppt, with 2 stacked events. Historical outputs are retained as measured pipeline evidence. QLP selected-kind fitted median17.722ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35809488423761389440, P=18.1258785067±0.0037695277d, e=0.396175, omega=68.1766deg. Closest edge-on conjunction offset-0.448298d (-0.024732phase), full-SB1-covariance linear propagated Gaia uncertainty0.750828d at the measured epoch. Near-Gaia-reference projected eclipse offset0.260801d (photometric period projection allowance0.090311d). The approximate central duration6.61h vs observed median3.80h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Two QLP measured events separated by four cycles give a conditional ephemeris. Independent raw cutout S39 centers2366.85039+/-0.00592 and2384.98788+/-0.00879 BTJD, separation18.13749+/-0.01060d, support same-kind adjacent-cycle recurrence near18.1224d; see helper/same-sector-refits.json. Alternative sector39 cutout shows target-centered deficit; nearest capable neighbor25.9arcsec. Alias search is bounded rather than exhaustive.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
100	135	4088.4759074	0.001340	18.914	usable; same-kind selection applies
103	139	4160.9655175	0.001157	16.530	usable; same-kind selection applies

TIC 314047448: PLAUSIBLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 2 distinct eclipse events in selected sectors[77, 85]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: conditional ephemeris; period not independently tested.** 2 same-kind midtimes give P=16.3753656517 ±0.0004502238d, reference eclipse epoch BTJD3397.5479750, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after check.** Historical S24 deficit peak[11, 8] vs target pixel[8, 8]; deficit-target separation13.232arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual1.000. Capable neighbours: Gaia 2013332341680377600: 27.20 arcsec, G14.774, required fractional eclipse0.083, pixel fractional loss0.00021165848446181757; Gaia 2013332513479061504: 34.61 arcsec, G16.402, required fractional eclipse0.348, pixel fractional loss-0.00028384734199898555; Gaia 2013332307320743040: 40.41 arcsec, G16.114, required fractional eclipse0.269, pixel fractional loss-0.0026636487312149573; Gaia 2013332513479058560: 45.31 arcsec, G14.753, required fractional eclipse0.081, pixel fractional loss-0.0030179173295920513; Gaia 2013332513479057792: 45.81 arcsec, G17.240, required fractional eclipse0.745, pixel fractional loss-0.0030179173295920513; Gaia 2013332238601177728: 47.17 arcsec, G16.121, required fractional eclipse0.270, pixel fractional loss-0.008904227173039583; Gaia 2013331517046673536: 50.32 arcsec, G15.943, required fractional eclipse0.230, pixel fractional loss-0.004864827679816797; Gaia 2013331517046676992: 58.04 arcsec, G15.929, required fractional eclipse0.227, pixel fractional loss-0.004864827679816797

4. **Alternative reduction: inconclusive after completed check.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths4.502/3.227/1.299ppt, with 2 stacked events. Poor S24 extraction for this target is explicitly inconclusive rather than a validated alternative eclipse recovery. QLP selected-kind fitted median8.026ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3201333234168038092 8, P=16.3692406983±0.0073099680d, e=0.373760, omega=242.9939deg. Closest edge-on conjunction offset1.057420d (0.064598phase), full-SB1-covariance linear propagated Gaia uncertainty1.336052d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.069571d (photometric period projection allowance0.082841d). The approximate central duration4.49h vs observed median4.08h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Historical sector24 deficit has large PSF residual and displaced bright-source structure; target attribution remains unresolved after completed independent helper audit. Only two long-separated raw events have usable timings, with no independent adjacent same-kind interval; the period is untested against integer-cycle alternatives, so the physical tier is PLAUSIBLE. Two measured QLP events fourteen historical cycles apart support timing conditional on integer-cycle assignment; alternative cycle aliases are not independently eliminated. The helper S24 cutout center fits failed (bounds/zero depth), not valid timings or nulls. Gaia conjunction offset0.0646phase has propagated uncertainty1.34d, not an arbitrary inconsistency veto.

Next check: Measure consecutive same-kind eclipses with resolved photometry to test the period and source attribution.

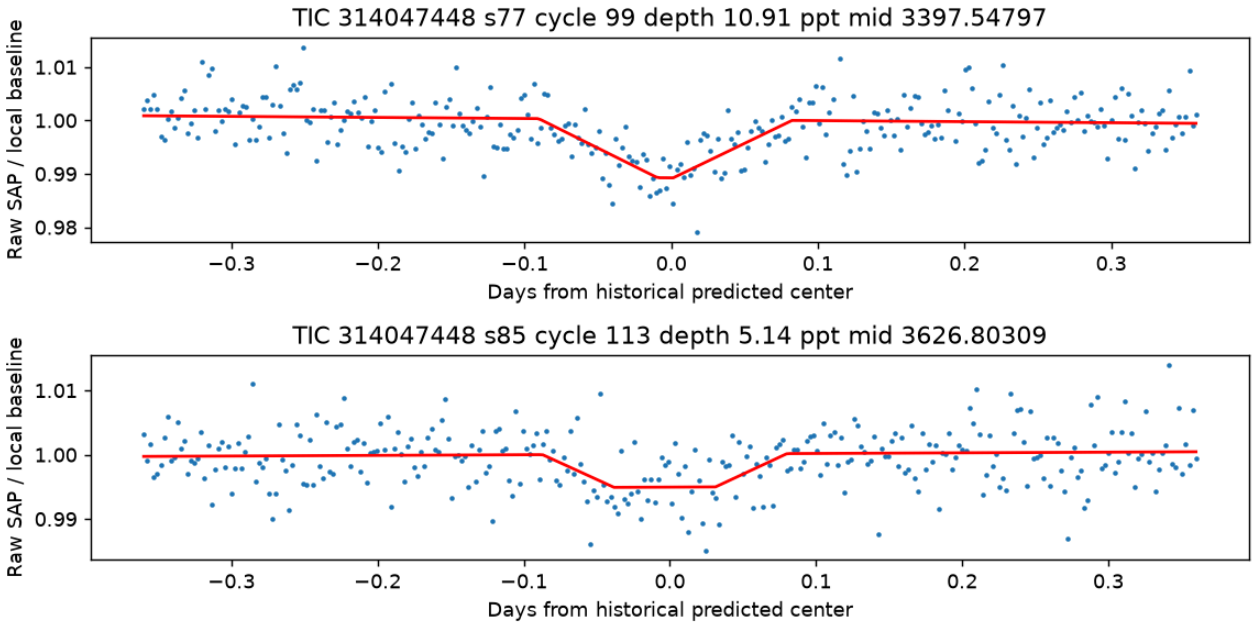
Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

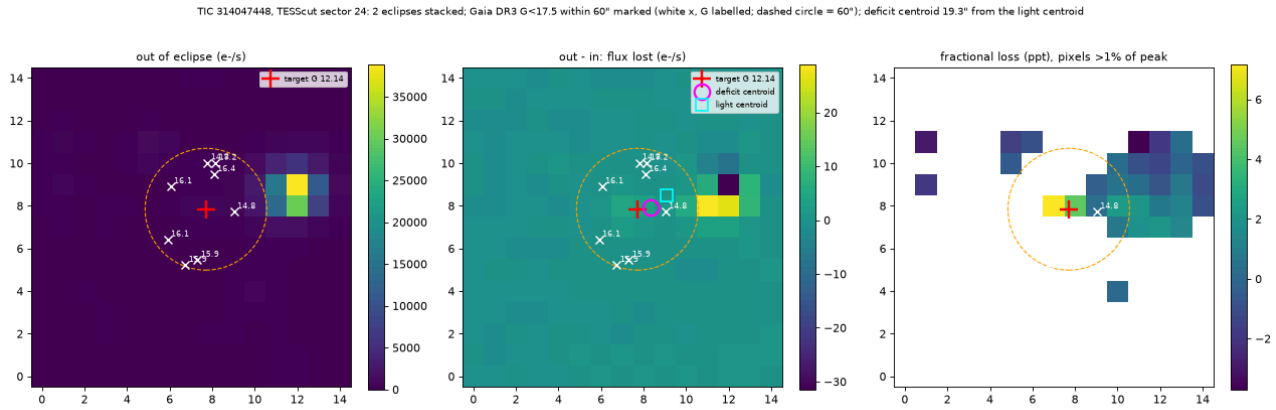
Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
77	99	3397.5479750	0.003385	10.914	usable; same-kind selection applies
85	113	3626.8030941	0.005317	5.138	usable; same-kind selection applies

Evidence (original source layout; use the public evidence links below for exported locations): ../helper/pixel-identity-audit.json, ../helper/same-sector-refits.json, ../helper/314047448-measured-diff.json, ../helper/48108063-measured-diff.json; measurements.json, raw-events.png, raw-windows.csv, shared-qlp QLP FITS; historical/diff_s24.json, historical/diff_s24.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R249. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R249; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.



R249; diff_s24.png. Target-pixel eclipse-deficit evidence; capable-neighbour and angular-resolution limitations remain in the full report.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 373621318: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[58, 85]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass with disclosed cycle assumptions.** 11 same-kind midtimes give P=4.1104208467 ±0.0000052818d, reference eclipse epoch BTJD2883.5677296, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S58 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation2.280arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.941. Capable neighbours: Gaia 511214808904243584: 30.05 arcsec, G14.117, required fractional eclipse0.169, pixel fractional loss0.004656160732442441; Gaia 511214052989995264: 33.49 arcsec, G13.916, required fractional eclipse0.145, pixel fractional loss0.0054985862487090705; Gaia 511214430947407872: 34.68 arcsec, G15.661, required fractional eclipse0.614, pixel fractional loss0.005682766497404662; Gaia 511214774544514560: 34.80 arcsec, G15.160, required fractional eclipse0.397, pixel fractional loss0.004714198414336461; Gaia 511214430947117824: 41.03 arcsec, G14.835, required fractional eclipse0.302, pixel fractional loss0.005682766497404662; Gaia 511214430947115264: 45.57 arcsec, G15.688, required fractional eclipse0.629, pixel fractional loss0.005682766497404662; Gaia 511214362227651712: 51.37 arcsec, G15.873, required fractional eclipse0.741, pixel fractional loss0.008128411725709894
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths26.264/17.422/6.989ppt, with 7 stacked events. Historical outputs are retained

as measured pipeline evidence. QLP selected-kind fitted median29.444ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3511214048684134528, P=4.1103587301±0.0002578027d, e=0.020847, omega=29.4745deg. Closest edge-on conjunction offset0.061699d (0.015011phase), full-SB1-covariance linear propagated Gaia uncertainty0.158656d at the measured epoch. Near-Gaia-reference projected eclipse offset0.023994d (photometric period projection allowance0.003206d). The approximate central duration6.16h vs observed median3.62h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated narrow eclipses and target-centered deficit favor target; bright field source affects whole-image PSF residual and dilution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
58	0	2883.5681774	0.001157	26.815	usable; same-kind selection applies

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 129765199: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[3, 97, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass with disclosed cycle assumptions.** 5 same-kind midtimes give P=18.2494315475 ±0.0000459899d, reference eclipse epoch BTJD1385.4630846, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S3 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.721arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.152. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths124.676/125.418/125.076ppt, with 2 stacked events. Historical outputs are retained as measured pipeline evidence. QLP selected-kind fitted median108.159ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3496399428727525900 8, P=18.2510587758±0.0033978994d, e=0.275285, omega=357.8710deg. Closest edge-on conjunction offset0.029584d (0.001621phase), full-SB1-covariance linear propagated Gaia uncertainty0.275262d at the measured epoch. Near-Gaia-reference projected eclipse offset0.119082d (photometric period projection allowance0.002529d). The approximate central duration10.13h vs observed median8.54h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeating eclipses, target-centered deficit, no capable catalogued neighbor. Sector-dependent depth is dilution or extraction dependent.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R252. TIC 309558046

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 309558046: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 9 distinct eclipse events in selected sectors[1, 37, 90]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass with disclosed cycle assumptions.** 6 same-kind midtimes give P=13.0830020618 ±0.0000240012d, reference eclipse epoch BTJD1331.6469978, kind: Deeper primary (even historical half-period cycles). Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S9 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.695arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.165. Capable neighbours: Gaia 5277988591691031808: 34.66 arcsec, G15.095, required fractional eclipse0.291, pixel fractional loss0.00740682275584591; Gaia 5277988660410508160: 41.05 arcsec, G16.170, required fractional eclipse0.751, pixel fractional loss0.00817955277592489; Gaia 5277988660410508928: 54.10 arcsec, G16.233, required fractional eclipse0.794, pixel fractional loss0.007053373948642565
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths13.627/14.520/14.475ppt, with 4 stacked events. Historical outputs are retained as measured pipeline evidence. QLP selected-kind fitted median26.962ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35277988587391544320, P=13.0837683530±0.0023013833d, e=0.018445, omega=309.8190deg. Closest edge-on conjunction

offset0.062058d (0.004743phase), full-SB1-covariance linear propagated Gaia uncertainty0.209431d at the measured epoch. Near-Gaia-reference projected eclipse offset0.117231d (photometric period projection allowance0.001728d). The approximate central duration17.77h vs observed median14.32h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipses approximately27/17ppt establish orbital period twice historical SAP half period. Even half-period cycles are deeper primaries and alone define ephemeris. Historical cutout stacks mixed eclipse kinds.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths7.796/6.963/6.200ppt, with 4 stacked events. Historical outputs are retained as measured pipeline evidence. QLP selected-kind fitted median9.231ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3606098806349131980 8, P=7.0622964355±0.0030493697d, e=0.116094, omega=132.3120deg. Closest edge-on conjunction offset-0.135760d (-0.019223phase), full-SB1-covariance linear propagated Gaia uncertainty0.531776d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.202362d (photometric period projection allowance0.012769d). The approximate central duration7.50h vs observed median8.33h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Capable neighbor at4.34arcsec needs49% eclipse. Deficit0.073pixel from target favors target, but close separation and uncalibrated centroid cannot securely exclude neighbor. Completed review retains probable attribution.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry / multi-source PRF localization

Archived source: sanitized report text.

TIC 124007093: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors[7, 61, 89]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass with disclosed cycle assumptions.** 7 same-kind midtimes give P=10.0645223865 ±0.0000700239d, reference eclipse epoch BTJD1500.7378621, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after check.** Historical S62 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.581arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.749. Capable neighbours: Gaia 5535503079732178432: 18.57 arcsec, G13.455, required fractional eclipse0.083, pixel fractional loss0.013268088594969267; Gaia 5535503281596254080: 19.22 arcsec, G15.535, required fractional eclipse0.449, pixel fractional loss0.014072376440044656; Gaia 5535526543139207808: 41.15 arcsec, G16.294, required fractional eclipse0.882, pixel fractional loss0.0017686528954465618; Gaia 5535526478714025856: 49.25 arcsec, G14.345, required fractional eclipse0.163, pixel fractional loss0.009145411171091576; Gaia 5535503045372439808: 50.59 arcsec, G16.074, required fractional eclipse0.724, pixel fractional loss0.007014614314219571; Gaia 5535503320250307712: 54.31 arcsec, G16.374, required fractional eclipse0.948, pixel fractional loss-0.0010512912208078477
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths16.996/15.975/13.665ppt, with 3 stacked events. Historical outputs are retained as measured pipeline evidence. QLP selected-kind fitted median21.330ppt. This separately extracted

cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3553503075428606976, P=10.0674356008±0.0026207857d, e=0.038103, omega=258.4752deg. Closest edge-on conjunction offset-0.334392d (-0.033215phase), full-SB1-covariance linear propagated Gaia uncertainty0.335271d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.013938d (photometric period projection allowance0.007703d). The approximate central duration13.86h vs observed median13.00h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Long eclipses coexist with baseline variability; free local linear fits and conservative timing errors preserve its contribution. Target-centered cutout deficit0.17pixel from target favors target, but nearest capable neighbor18.57arcsec needs only8.3% eclipse, and PSF residual0.75 without calibrated centroid uncertainty leaves attribution unresolved. Independent optimizer timing centers differ by up to0.0152d; model systematics are not total-error calibrated.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 30753325: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[64, 102]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass with disclosed cycle assumptions.** 8 same-kind midtimes give P=3.8144612029 ±0.0000028664d, reference eclipse epoch BTJD3043.2158652, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S37 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.566arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.353. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths58.070/57.472/55.477ppt, with 6 stacked events. Historical outputs are retained as measured pipeline evidence. QLP selected-kind fitted median58.989ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3616566906087424998 4, P=3.8146327900±0.0002474851d, e=0.061242, omega=70.4217deg. Closest edge-on conjunction offset-0.055060d (-0.014434phase), full-SB1-covariance linear propagated Gaia uncertainty0.155049d at the measured epoch. Near-Gaia-reference projected eclipse offset0.064365d (photometric period projection allowance0.001995d). The approximate central

duration4.07h vs observed median2.74h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Clean triangular repeating eclipses, target-centered deficit and no capable catalogued neighbor. Depth changes between sectors; no intrinsic undiluted depth inferred.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry / multi-source PRF localization

Archived source: sanitized report text.

TIC 48108063: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 10 distinct eclipse events in selected sectors[35, 62, 89]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass with disclosed cycle assumptions.** 10 same-kind midtimes give P=5.7972370881 ±0.0000058204d, reference eclipse epoch BTJD2272.5117326, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after check.** Historical S62 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation0.764arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.508. Capable neighbours: Gaia 5439164283215218688: 15.01 arcsec, G11.053, required fractional eclipse0.183, pixel fractional loss0.03502751096712482
4. **Alternative reduction: eclipse recovered with depth discrepancy.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths35.028/31.419/31.304ppt, with 4 stacked events. Historical outputs are retained as measured pipeline evidence. QLP selected-kind fitted median139.304ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3543916428321802188 8, P=5.7969445240±0.0002979833d, e=0.091414, omega=170.9390deg. Closest edge-on conjunction offset0.077140d (0.013307phase), full-SB1-covariance linear propagated Gaia uncertainty0.096630d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.017943d (photometric period

projection allowance0.001892d). The approximate central duration5.41h vs observed median4.53h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep raw eclipses approximately134-143ppt. Independent measured-ephemeris S62 cutout re-extraction gives3x3 core deficit26.5ppt and1x1 32.1ppt; the factor4-5 contrast persists. Dilution and extraction differences are possible, unestablished explanations. Deficit0.036pixel from target vs neighbor0.72pixel favors target, but15arcsec capable neighbor and uncalibrated centroid leave interpretation unresolved.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R257. TIC 377389892

physical_verdict: CONFIRMED

novelty_status: known prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 377389892: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[21, 48, 75]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=4.5881927790 +/-0.0000096916d, reference eclipse epoch BTJD1875.0768278, kind: Deeper primary; shallower secondary at orbital phase0.5. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Deciding S21 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.123arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.044. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths228.894/227.798/226.259ppt, with 4 stacked events. QLP selected-kind fitted median227.447ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3854441274902991616, P=4.5880638447+/-0.0001891317d, e=0.018288, omega=77.4620deg. Closest edge-on conjunction offset0.028670d (0.006249phase), full-SB1-covariance linear propagated Gaia uncertainty0.068238d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.013105d (photometric period projection allowance0.003140d). The approximate central duration5.18h vs observed median4.54h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Known VSX EA within0.02arcsec; excluded from new-system count. Catalogue1.147d is a quarter-period alias: raw fold shows deeper primary each4.588d and shallower secondary at phase0.5. Fold at1.147d mixes out-of-eclipse and unequal eclipse points. Primary epoch identifies deeper eclipse; physical Gaia orbit association retained.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry / multi-source PRF localization

Archived source: sanitized report text.

TIC 88811793: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 10 distinct eclipse events in selected sectors[13, 93, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 10 same-kind midtimes give P=7.4357138600 +/-0.0000172221d, reference eclipse epoch BTJD1660.0553916, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after check.** Deciding S93 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation1.829arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.732. Capable neighbours: Gaia 6721228062775457920: 14.54 arcsec, G12.652, required fractional eclipse0.161, pixel fractional loss0.024512582723309626; Gaia 6721225146508733184: 27.33 arcsec, G10.653, required fractional eclipse0.078, pixel fractional loss0.002358223522502439
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths44.826/23.910/14.579ppt, with 4 stacked events. QLP selected-kind fitted median63.740ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3672122806277545830 4, P=7.4358869328+/-0.0013790350d, e=0.068823, omega=310.9380deg. Closest edge-on conjunction offset0.081898d (0.011014phase), full-SB1-covariance linear propagated Gaia uncertainty0.348216d at the measured epoch. Near-Gaia-reference projected eclipse offset0.111493d (photometric period projection allowance0.002945d). The approximate central duration9.19h vs

observed median7.58h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unresolved close-neighbor attribution after completed check. Capable neighbor14.54arcsec away lies0.75pixel from deficit centroid; target is0.087pixel away. Another capable neighbor27.33arcsec away is spatially distinct. Deficit favors target, but no calibrated multi-source PRF localization excludes the closest source. Strong aperture dilution: cutout45/24/15ppt versus QLP approximately60ppt. Pixel fractional loss is blended light, not source-intrinsic required eclipse.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
13	0	1660.0504423	0.010416	63.001	usable; same-kind selection applies

TIC 467753507: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors[59, 86]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=9.9441928263 +/-0.0000158531d, reference eclipse epoch BTJD2917.6341831, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Deciding S43 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.668arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.200. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths29.800/29.222/27.872ppt, with 2 stacked events. QLP selected-kind fitted median30.155ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3169109080240209408, P=9.9436342684+/-0.0008415654d, e=0.604192, omega=278.8133deg. Closest edge-on conjunction offset0.155462d (0.015634phase), full-SB1-covariance linear propagated Gaia uncertainty0.239090d at the measured epoch. Near-Gaia-reference projected eclipse offset0.013589d (photometric period projection allowance0.004027d). The approximate central duration3.75h vs observed median2.49h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four measured eclipses in two representative sectors; no capable neighbor. Alternative cutout approximately29ppt agrees raw26-31ppt. Epoch identifies the repeating selected eclipse, deeper-secondary identity not established.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 350760292: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors[92]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=4.6960724668 +/-0.0003660296d, reference eclipse epoch BTJD3805.7766806, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Deciding S92 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation5.064arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.936. Capable neighbours: Gaia 4100891781366788480: 26.14 arcsec, G15.354, required fractional eclipse0.898, pixel fractional loss0.06433309025869284; Gaia 4100894839383543040: 50.66 arcsec, G15.125, required fractional eclipse0.738, pixel fractional loss0.000569337846151796; Gaia 4100894701944580480: 53.65 arcsec, G15.307, required fractional eclipse0.862, pixel fractional loss0.004018742576455143; Gaia 4100894701944566784: 55.28 arcsec, G15.175, required fractional eclipse0.770, pixel fractional loss0.035653750928356334
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths67.342/67.856/63.124ppt, with 4 stacked events. QLP selected-kind fitted median62.873ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3410089473630430536, P=4.6961323973+/-0.0007029011d, e=0.098920, omega=100.7554deg. Closest edge-on conjunction

offset0.039875d (0.008491phase), full-SB1-covariance linear propagated Gaia uncertainty0.540721d at the measured epoch. Near-Gaia-reference projected eclipse offset0.083505d (photometric period projection allowance0.266470d). The approximate central duration5.17h vs observed median3.28h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four raw repeats in available representative sector92; historical sector39 cutout independently reuses earlier observing occasions. Measured4.69607d differs screening4.69710d; short baseline and timing covariance retained. Capable nearest neighbor26.14arcsec away is1.45pixels from deficit centroid versus0.24pixel for target; other capable neighbors are50-55arcsec away. Poor total-light PSF residual0.936 reflects crowded light and is not sole attribution evidence.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R261. TIC 371241950

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 371241950: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 13 distinct eclipse events in selected sectors[10, 38, 90]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 13 same-kind midtimes give P=5.8085988833 +/-0.0000066634d, reference eclipse epoch BTJD1575.3856200, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Deciding S90 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.325arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.363. Capable neighbours: Gaia 5243963620257188736: 45.52 arcsec, G14.028, required fractional eclipse0.536, pixel fractional loss0.017013504837050105
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths80.317/75.007/63.791ppt, with 4 stacked events. QLP selected-kind fitted median83.558ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35243963688976670592, P=5.8081279932+/-0.0004474477d, e=0.047392, omega=328.0911deg. Closest edge-on conjunction offset0.172284d (0.029663phase), full-SB1-covariance linear propagated Gaia uncertainty0.095187d at the measured epoch. Near-Gaia-reference projected eclipse offset0.076223d (photometric period projection allowance0.001359d). The approximate central duration7.35h vs observed median4.34h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Thirteen measured repeats span three sectors; capable neighbor45.52arcsec is spatially separated from deficit core. Gaia phase offset0.030 is discussed with covariance rather than arbitrary cutoff; observed4.3h duration can be noncentral.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 407207285: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors[17, 25, 85]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=12.8149004912 +/-0.0000392303d, reference eclipse epoch BTJD1767.6750368, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Deciding S17 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation2.991arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.606. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths69.282/68.374/67.489ppt, with 2 stacked events. QLP selected-kind fitted median67.187ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3529579745461206016, P=12.8145405975+/-0.0008878672d, e=0.052468, omega=134.5472deg. Closest edge-on conjunction offset0.164534d (0.012840phase), full-SB1-covariance linear propagated Gaia uncertainty0.104311d at the measured epoch. Near-Gaia-reference projected eclipse offset0.125665d (photometric period projection allowance0.004237d). The approximate central duration36.58h vs observed median21.65h permits noncentral geometry; this radius/minimum-mass estimate is not a

detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Historical0.18d duration placed out-of-eclipse windows inside the approximately0.90d eclipse and suppressed cutout depth to6ppt. Revised21.6h extraction yields69/68/67ppt versus raw median67ppt. Updated flux budget makes all neighbors incapable (closest18.27arcsec requires253percent intrinsic eclipse). Target-centered revised deficit passes attribution; original extraction preserved. Raw fit uses0.65d baseline exclusion and free duration; no unperformed check is hidden.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

Archived source: sanitized report text.

TIC 177257211: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 17 distinct eclipse events in selected sectors[1, 38, 98]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 17 same-kind midtimes give P=3.5443290949 +/-0.0000030739d, reference eclipse epoch BTJD1329.0245577, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Deciding S97 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.827arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.403. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths62.101/59.341/55.456ppt, with 16 stacked events. QLP selected-kind fitted median55.820ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3526087417350849088O, P=3.5442836835+/-0.0003211078d, e=0.026413, omega=251.8290deg. Closest edge-on conjunction offset0.042646d (0.012032phase), full-SB1-covariance linear propagated Gaia uncertainty0.104328d at the measured epoch. Near-Gaia-reference projected eclipse offset0.030612d (photometric period projection allowance0.000815d). The approximate central duration5.70h vs observed median3.57h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Seventeen raw repeated events across three sectors; no capable neighbor. Target-centered deficit and56-62ppt cutout/raw amplitudes. Historical253 events are screening statistics, not measured timing count.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 29114881: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors[43, 45, 72]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=12.6025319623 +/-0.0000314390d, reference eclipse epoch BTJD2478.4844056, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Deciding S43 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation2.217arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.315. Capable neighbours: Gaia 3403151219984383616: 53.54 arcsec, G14.899, required fractional eclipse0.579, pixel fractional loss0.010934079114229483
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths57.519/56.424/51.492ppt, with 2 stacked events. QLP selected-kind fitted median57.390ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3340314534446912678 4, P=12.5997639477+/-0.0076575857d, e=0.081743, omega=206.9858deg. Closest edge-on conjunction offset0.028161d (0.002235phase), full-SB1-covariance linear propagated Gaia uncertainty1.025084d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.431329d (photometric period projection allowance0.005219d). The approximate central duration6.14h vs observed median5.33h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Six raw events across three sectors. Capable neighbor53.54arcsec is distinct from target-centered deficit. Raw56-59ppt and cutout57/56/51ppt depend on aperture.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 77605102: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[9, 62, 99]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=11.2688089976 +/-0.0000140630d, reference eclipse epoch BTJD1548.9000776, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Deciding S62 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation4.232arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.760. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths146.819/143.733/133.360ppt, with 3 stacked events. QLP selected-kind fitted median167.856ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3542419968514814924 8, P=11.2714186464+/-0.0039065215d, e=0.591502, omega=296.0774deg. Closest edge-on conjunction offset-0.297978d (-0.026437phase), full-SB1-covariance linear propagated Gaia uncertainty0.256542d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.029184d (photometric period projection allowance0.001448d). The approximate central duration4.83h vs observed median4.63h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Five repeated raw eclipses across three sectors; no capable neighbor. Raw145-169ppt and cutout147/144/133ppt show extraction dependence. Geometry offset minus0.026phase retained with propagated Gaia covariance; not sigma veto.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 35635884: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[33, 87]. The raw-event plot and numeric raw-windows.csv were inspected. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=5.5005487862 +/-0.0000107720d, reference eclipse epoch BTJD2203.8207426, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Deciding S33 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.630arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.454. Capable neighbours: Gaia 2946315752238013696: 47.20 arcsec, G13.768, required fractional eclipse0.566, pixel fractional loss0.009677394392040716
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths116.027/108.058/81.954ppt, with 4 stacked events. QLP selected-kind fitted median117.741ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3294631536998117478 4, P=5.5005719282+/-0.0003916036d, e=0.166765, omega=78.6462deg. Closest edge-on conjunction offset-0.008812d (-0.001602phase), full-SB1-covariance linear propagated Gaia uncertainty0.131948d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.001175d (photometric period projection allowance0.003555d). The approximate central duration4.36h vs observed median3.34h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Eight repeated raw eclipses across three sectors; capable neighbor47.20arcsec is distinct from deficit core. Raw114-129ppt vs cutout116/108/82ppt show aperture and sector dilution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

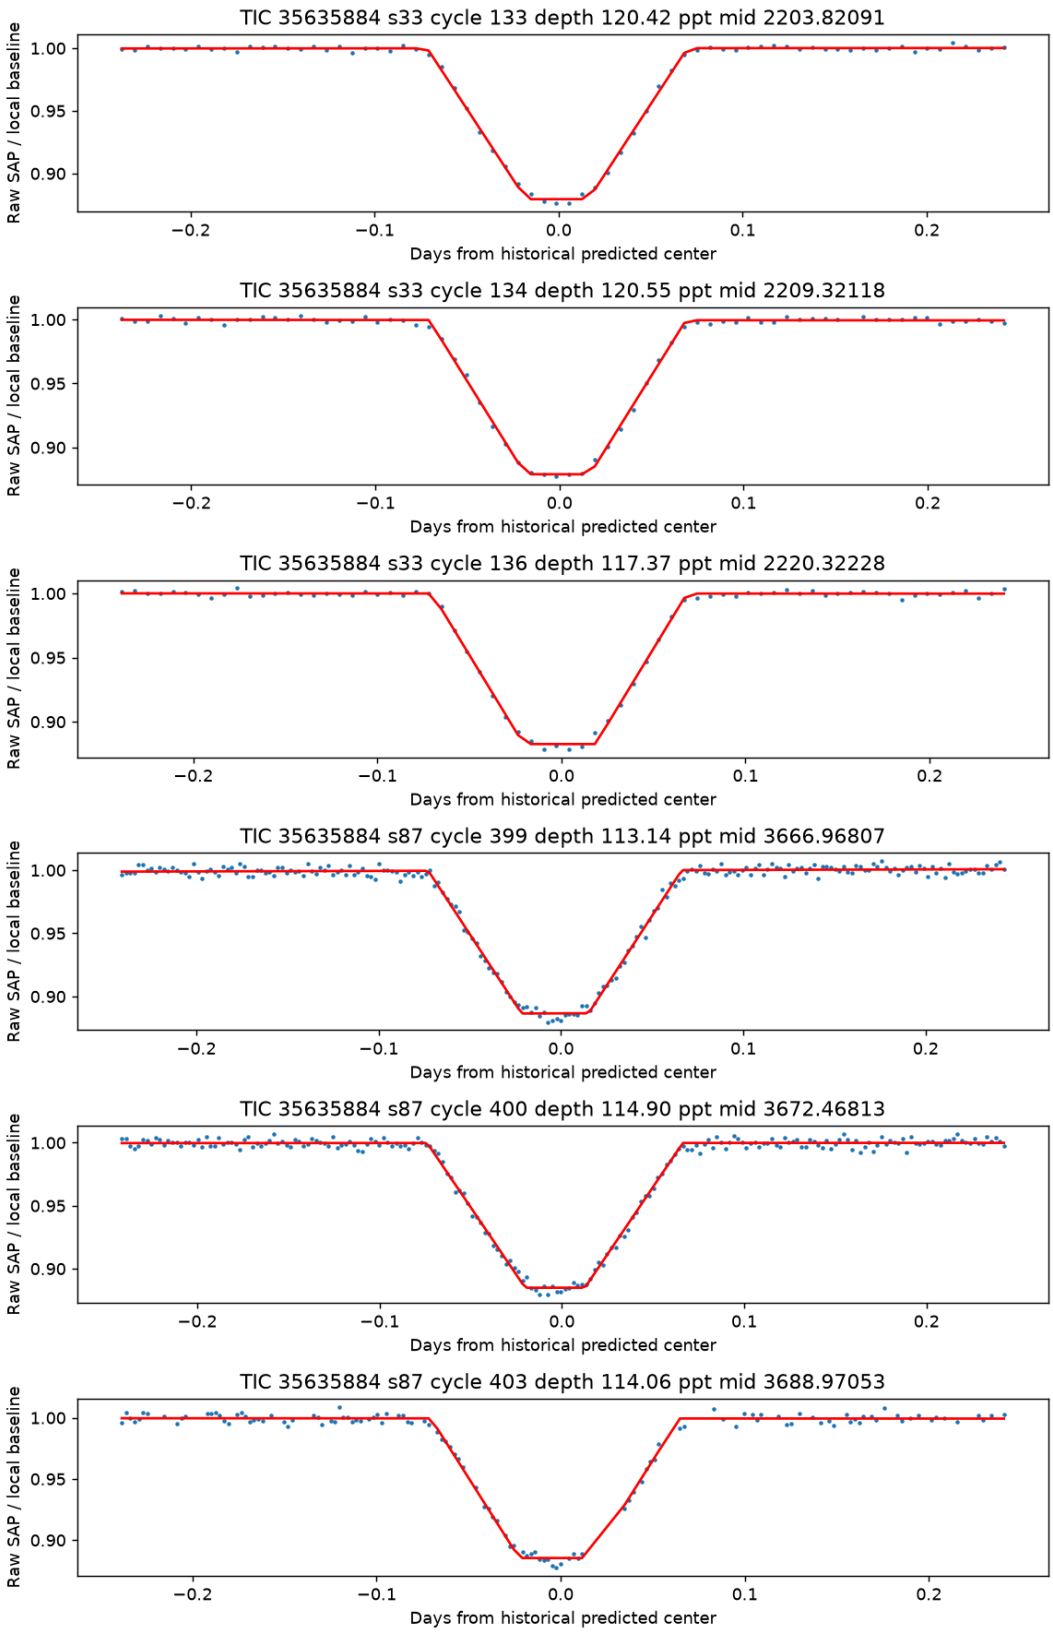
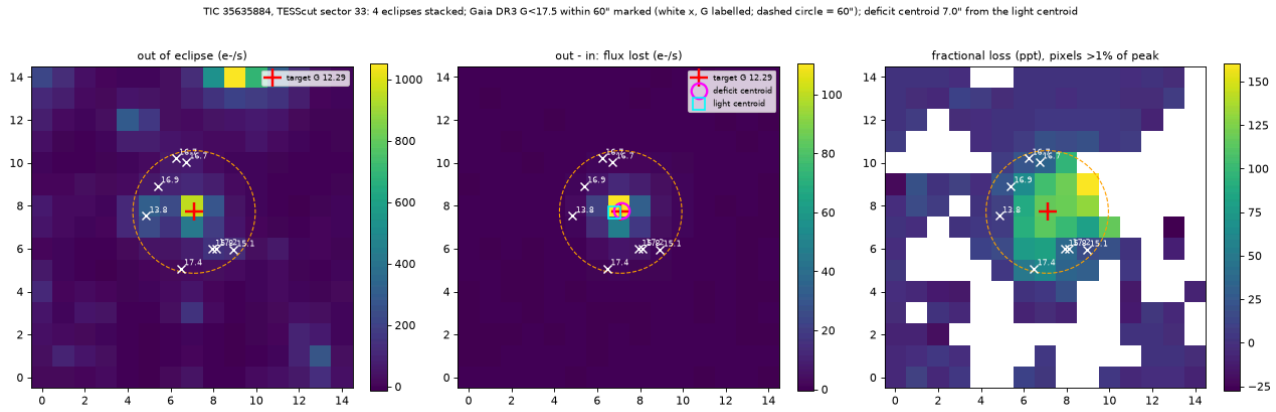
Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, ../identity-check.json, shared-qlp QLP FITS; historical/diff_s33.json, historical/diff_s33.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] For TIC407207285 the deciding revised cutout is revised-cutout/diff_revised-long-window.json and .png; historical extraction remains for comparison. Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R266. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R266; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.



R266; diff_s33.png. Target-pixel eclipse-deficit evidence; capable-neighbour and angular-resolution limitations remain in the full report.

R267. TIC 396859601

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization; no missing bounded admission check.

Archived source: sanitized report text.

TIC 396859601: CONFIRMED

Full bounded review COMPLETE under current paper section2.7. Historical screened status was not an admission. Catalogue novelty is separate; central seven-group coverage applies, see ../../catalogues/coverage-matrix.csv. No exhaustive priority claim.

1. **Raw repeated eclipses: pass.** 3 directly measured raw QLP SAP events in sectors[5, 32]. Representative raw-event plots and numeric windows inspected. A local linear baseline plus free trapezoid was fitted to quality-zero cadences. Predicted centers only guide windows. Flagged/uncovered windows are not clean non-detections. At most three spread QLP sectors used; no mandatory all-event/all-sector fitting.
2. **Timing: pass with limitations below.** 2 same-kind measured times give P=16.77770105414 +/-0.00491037467d, reference eclipse epoch BTJD2179.72210646; epoch kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Historical photometric cycle branch guides association, not a fixed Gaia period fit. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. SparseS21 TIC20176241 instead uses duration/2 conservative allowance. Zero/singular timing fits are excluded; their real raw detections remain evidence. This is not a blind all-alias search.
3. **Attribution: pass at TESS image resolution with limitations below.** DecidingS32 image peak[7, 8] matches target pixel[7, 8]; target-deficit offset0.112pixel, light-deficit offset1.611arcsec; PSF total-light scaled residual0.138. Gaia identifiers/WCS validated in identity-check.json (zero pixel mismatch). Capable neighbors listed below; required eclipse is approximate Gaia-G flux budget and pixel fractional losses are blended, not intrinsic source eclipses.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut yields1x1/3x3/5x5 depths18.583/18.905/18.782ppt, 2 stacked events, versus selected-kind raw QLP median18.238ppt. Aperture dilution and mixed primary/secondary stacks may change depth. Reused numeric image and plots, cutout identity and source algorithm checked; same TESS photons test reduction robustness, not independent observing occasions.
5. **Gaia geometry: consistent within stated model limitations.** DR33258578909949773056; P=16.7849273877 +/-0.0081647730d, e=0.285924, omega=191.4077deg. Closest edge-on conjunction offset-0.376136d (-0.022409phase), full-SB1-covariance linear Gaia uncertainty1.029050d at measured epoch. Approximate central duration7.28h vs measured median2.24h permits noncentral eclipses. Mass function0.027170solar, assumed primary mass1.05,

minimum companion0.382solar. This is not a detailed binary fit or an arbitrary sigma veto; correlation convention and near-reference sensitivity recorded in ../gaia-geometry.json.

Deciding limitations: Two S32 well-sampled events determine the reported period. A third real S5 eclipse tests recurrence across 44 cycles; its zero/singular covariance is excluded from timing. No newer timeseries sectors in current MAST query beyond5/32. Period error remains short-baseline and conditional on tested cycle branch, not precision long-baseline characterization.

Next check: Optional precision characterization; no missing bounded admission check.

Sector	Historical photometric cycle	Measured midpoint BTJD	Input timing error d	Depth ppt	Usable timing before same-kind selection

next_check: Optional precision characterization; no missing bounded admission check.

Archived source: sanitized report text.

TIC 115106052: CONFIRMED

Full bounded review COMPLETE under current paper section2.7. Historical screened status was not an admission. Catalogue novelty is separate; central seven-group coverage applies, see ../../catalogues/coverage-matrix.csv. No exhaustive priority claim.

1. **Raw repeated eclipses: pass.** 15 directly measured raw QLP SAP events in sectors[1, 68, 95]. Representative raw-event plots and numeric windows inspected. A local linear baseline plus free trapezoid was fitted to quality-zero cadences. Predicted centers only guide windows. Flagged/uncovered windows are not clean non-detections. At most three spread QLP sectors used; no mandatory all-event/all-sector fitting.
2. **Timing: pass with limitations below.** 10 same-kind measured times give P=7.64111642841 +/-0.00000850037d, reference eclipse epoch BTJD1329.80183865; epoch kind: Deeper primary: odd half-period cycles. Historical photometric cycle branch guides association, not a fixed Gaia period fit. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. SparseS21 TIC20176241 instead uses duration/2 conservative allowance. Zero/singular timing fits are excluded; their real raw detections remain evidence. This is not a blind all-alias search.
3. **Attribution: pass at TESS image resolution with limitations below.** DecidingS27 image peak[7, 8] matches target pixel[7, 8]; target-deficit offset0.199pixel, light-deficit offset0.464arcsec; PSF total-light scaled residual0.237. Gaia identifiers/WCS validated in identity-check.json (zero pixel mismatch). Capable neighbors listed below; required eclipse is approximate Gaia-G flux budget and pixel fractional losses are blended, not intrinsic source eclipses.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut yields1x1/3x3/5x5 depths64.129/63.115/61.825ppt, 5 stacked events, versus selected-kind raw QLP median69.362ppt. Aperture dilution and mixed primary/secondary stacks may change depth. Reused numeric image and plots, cutout identity and source algorithm checked; same TESS photons test reduction robustness, not independent observing occasions.
5. **Gaia geometry: consistent within stated model limitations.** DR3677443219349133504O; P=7.6419883813 +/-0.0004853004d, e=0.050448, omega=186.4256deg. Closest edge-on conjunction offset0.054355d (0.007113phase), full-SB1-covariance linear Gaia uncertainty0.075422d at measured epoch. Approximate central duration9.39h vs measured median5.84h permits noncentral eclipses. Mass function0.174560solar, assumed primary mass1.1, minimum companion0.882solar. This is not a detailed binary fit or an arbitrary sigma veto; correlation convention and near-reference sensitivity recorded in ../gaia-geometry.json.

Deciding limitations: Deeper odd half-period cycles selected:10 primary times, with independent even-cycle timing agreement. Alternating depth and center residuals support doubled orbital period; historical half-period stack mixes unequal eclipses.

Next check: Optional precision characterization; no missing bounded admission check.

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization; no missing bounded admission check.

Archived source: sanitized report text.

TIC 144113939: CONFIRMED

Full bounded review COMPLETE under current paper section2.7. Historical screened status was not an admission. Catalogue novelty is separate; central seven-group coverage applies, see ../../catalogues/coverage-matrix.csv. No exhaustive priority claim.

1. **Raw repeated eclipses: pass.** 4 directly measured raw QLP SAP events in sectors[64, 101]. Representative raw-event plots and numeric windows inspected. A local linear baseline plus free trapezoid was fitted to quality-zero cadences. Predicted centers only guide windows. Flagged/uncovered windows are not clean non-detections. At most three spread QLP sectors used; no mandatory all-event/all-sector fitting.
2. **Timing: pass with limitations below.** 4 same-kind measured times give P=11.78879640721 +/-0.00001285928d, reference eclipse epoch BTJD3046.67692883; epoch kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Historical photometric cycle branch guides association, not a fixed Gaia period fit. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. SparseS21 TIC20176241 instead uses duration/2 conservative allowance. Zero/singular timing fits are excluded; their real raw detections remain evidence. This is not a blind all-alias search.
3. **Attribution: pass at TESS image resolution with limitations below.** DecidingS37 image peak[8, 7] matches target pixel[8, 7]; target-deficit offset0.135pixel, light-deficit offset2.607arcsec; PSF total-light scaled residual0.442. Gaia identifiers/WCS validated in identity-check.json (zero pixel mismatch). Capable neighbors listed below; required eclipse is approximate Gaia-G flux budget and pixel fractional losses are blended, not intrinsic source eclipses.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut yields1x1/3x3/5x5 depths36.457/35.553/33.835ppt, 2 stacked events, versus selected-kind raw QLP median35.558ppt. Aperture dilution and mixed primary/secondary stacks may change depth. Reused numeric image and plots, cutout identity and source algorithm checked; same TESS photons test reduction robustness, not independent observing occasions.
5. **Gaia geometry: consistent within stated model limitations.** DR3614687627685199104; P=11.7889746135 +/-0.0024534753d, e=0.061265, omega=283.7125deg. Closest edge-on conjunction offset-0.011443d (-0.000971phase), full-SB1-covariance linear Gaia uncertainty0.581526d at measured epoch. Approximate central duration5.96h vs measured median3.13h permits noncentral eclipses. Mass function0.108096solar, assumed primary mass0.96,

minimum companion0.656solar. This is not a detailed binary fit or an arbitrary sigma veto; correlation convention and near-reference sensitivity recorded in ../gaia-geometry.json.

Deciding limitations: One capable neighbor38.54arcsec away is separated from target-centered deficit. Four raw repeated events span sectors64/101; alternative historicalS37 provides earlier reduction evidence.

Next check: Optional precision characterization; no missing bounded admission check.

1. **Raw repeated eclipses: pass.** 4 directly measured raw QLP SAP events in sectors[95, 103]. Representative raw-event plots and numeric windows inspected. A local linear baseline plus free trapezoid was fitted to quality-zero cadences. Predicted centers only guide windows. Flagged/uncovered windows are not clean non-detections. At most three spread QLP sectors used; no mandatory all-event/all-sector fitting.
2. **Timing: pass with limitations below.** 4 same-kind measured times give P=7.13460231510 +/-0.00003044773d, reference eclipse epoch BTJD3886.00718979; epoch kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Historical photometric cycle branch guides association, not a fixed Gaia period fit. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. SparseS21 TIC20176241 instead uses duration/2 conservative allowance. Zero/singular timing fits are excluded; their real raw detections remain evidence. This is not a blind all-alias search.
3. **Attribution: pass at TESS image resolution with limitations below.** DecidingS102 image peak[8, 7] matches target pixel[8, 7]; target-deficit offset0.168pixel, light-deficit offset1.974arcsec; PSF total-light scaled residual0.382. Gaia identifiers/WCS validated in identity-check.json (zero pixel mismatch). Capable neighbors listed below; required eclipse is approximate Gaia-G flux budget and pixel fractional losses are blended, not intrinsic source eclipses.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut yields1x1/3x3/5x5 depths31.120/30.815/29.768ppt, 4 stacked events, versus selected-kind raw QLP median27.000ppt. Aperture dilution and mixed primary/secondary stacks may change depth. Reused numeric image and plots, cutout identity and source algorithm checked; same TESS photons test reduction robustness, not independent observing occasions.
5. **Gaia geometry: consistent within stated model limitations.** DR3649438507436423257 6; P=7.1343937492 +/-0.0007271545d, e=0.040070, omega=215.9747deg. Closest edge-on conjunction offset0.004981d (0.000698phase), full-SB1-covariance linear Gaia uncertainty0.330956d at measured epoch. Approximate central duration5.85h vs measured median2.83h permits noncentral eclipses. Mass function0.055553solar, assumed primary mass1.03, minimum companion0.509solar.

This is not a detailed binary fit or an arbitrary sigma veto; correlation convention and near-reference sensitivity recorded in ../gaia-geometry.json.

Deciding limitations: Four raw events in sectors95/103; target-centeredS102 cutout supports separate reduction. No capable neighbor within60arcsec.

Next check: Optional precision characterization; no missing bounded admission check.

Sector	Historical photometric cycle	Measured midpoint BTJD	Input timing error d	Depth ppt	Usable timing before same-kind selection

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry or calibrated multisource PRF localization.

Archived source: sanitized report text.

TIC 207813753: PROBABLE

Full bounded review COMPLETE under current paper section2.7. Historical screened status was not an admission. Catalogue novelty is separate; central seven-group coverage applies, see ../../catalogues/coverage-matrix.csv. No exhaustive priority claim.

1. **Raw repeated eclipses: pass.** 9 directly measured raw QLP SAP events in sectors[12, 93, 103]. Representative raw-event plots and numeric windows inspected. A local linear baseline plus free trapezoid was fitted to quality-zero cadences. Predicted centers only guide windows. Flagged/uncovered windows are not clean non-detections. At most three spread QLP sectors used; no mandatory all-event/all-sector fitting.
2. **Timing: pass with limitations below.** 9 same-kind measured times give P=5.40796620007 +/-0.00005411377d, reference eclipse epoch BTJD1648.61982916; epoch kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Historical photometric cycle branch guides association, not a fixed Gaia period fit. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. SparseS21 TIC20176241 instead uses duration/2 conservative allowance. Zero/singular timing fits are excluded; their real raw detections remain evidence. This is not a blind all-alias search.
3. **Attribution: unresolved after performed check.** DecidingS39 image peak[7, 7] matches target pixel[7, 7]; target-deficit offset0.057pixel, light-deficit offset19.218arcsec; PSF total-light scaled residual0.994. Gaia identifiers/WCS validated in identity-check.json (zero pixel mismatch). Capable neighbors listed below; required eclipse is approximate Gaia-G flux budget and pixel fractional losses are blended, not intrinsic source eclipses.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut yields1x1/3x3/5x5 depths29.314/16.217/3.548ppt, 5 stacked events, versus selected-kind raw QLP median32.832ppt. Aperture dilution and mixed primary/secondary stacks may change depth. Reused numeric image and plots, cutout identity and source algorithm checked; same TESS photons test reduction robustness, not independent observing occasions.
5. **Gaia geometry: consistent within stated model limitations.** DR3583521895442183782 4; P=5.4075148223 +/-0.0012803780d, e=0.091258, omega=234.4079deg. Closest edge-on conjunction offset-0.005827d (-0.001078phase), full-SB1-covariance linear Gaia uncertainty0.330001d at measured epoch. Approximate central duration8.60h vs measured median5.26h permits noncentral eclipses. Mass function0.025727solar, assumed primary mass1.03,

minimum companion0.369solar. This is not a detailed binary fit or an arbitrary sigma veto; correlation convention and near-reference sensitivity recorded in ../gaia-geometry.json.

Deciding limitations: Completed attribution check remains unresolved:16 capable neighbors, including12.72–18.90arcsec sources. Target-centered deficit favors target but lacks calibrated multistar localization to rule out close sources. Aperture depths differ strongly in crowded field. Real repeating eclipses retained probable.

Next check: Resolved eclipse photometry or calibrated multisource PRF localization.

TIC 173040554: PROBABLE

Full bounded review COMPLETE under current paper section2.7. Historical screened status was not an admission. Catalogue novelty is separate; central seven-group coverage applies, see ../../catalogues/coverage-matrix.csv. No exhaustive priority claim.

1. **Raw repeated eclipses: pass.** 36 directly measured raw QLP SAP events in sectors[33, 87]. Representative raw-event plots and numeric windows inspected. A local linear baseline plus free trapezoid was fitted to quality-zero cadences. Predicted centers only guide windows. Flagged/uncovered windows are not clean non-detections. At most three spread QLP sectors used; no mandatory all-event/all-sector fitting.
2. **Timing: pass with limitations below.** 17 same-kind measured times give P=2.35330880019 +/-0.00000483332d, reference eclipse epoch BTJD2203.63257783; epoch kind: Selected even half-period conjunction; usually deeper, identity provisional. Historical photometric cycle branch guides association, not a fixed Gaia period fit. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. SparseS21 TIC20176241 instead uses duration/2 conservative allowance. Zero/singular timing fits are excluded; their real raw detections remain evidence. This is not a blind all-alias search.
3. **Attribution: unresolved after performed check.** DecidingS33 image peak[8, 8] matches target pixel[8, 8]; target-deficit offset0.369pixel, light-deficit offset17.224arcsec; PSF total-light scaled residual0.818. Gaia identifiers/WCS validated in identity-check.json (zero pixel mismatch). Capable neighbors listed below; required eclipse is approximate Gaia-G flux budget and pixel fractional losses are blended, not intrinsic source eclipses.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut yields1x1/3x3/5x5 depths3.864/2.872/1.354ppt, 20 stacked events, versus selected-kind raw QLP median6.434ppt. Aperture dilution and mixed primary/secondary stacks may change depth. Reused numeric image and plots, cutout identity and source algorithm checked; same TESS photons test reduction robustness, not independent observing occasions.
5. **Gaia geometry: consistent within stated model limitations.** DR3292178275730627008O; P=2.3535060399 +/-0.0001121901d, e=0.044708, omega=342.5383deg. Closest edge-on conjunction offset-0.094204d (-0.040027phase), full-SB1-covariance linear Gaia uncertainty0.086885d at measured epoch. Approximate central duration6.29h vs measured median1.82h permits noncentral eclipses. Mass function0.115351solar, assumed primary mass1.77, minimum companion0.948solar. This is not a detailed binary fit or an arbitrary sigma veto; correlation convention and near-reference sensitivity recorded in ../gaia-geometry.json.

Deciding limitations: Seventeen selected even-half-cycle times; deeper ordering usually favors even but noisy shapes make primary identity provisional. Thirteen capable neighbors include13.75arcsec G13.70; centroid0.37pixel from target cannot exclude blended sources. Real raw alternating dips and orbital-period fit retained probable. Geometry phase offset-0.040 is discussed with Gaia covariance, not an automatic veto.

Next check: Resolved eclipse photometry or calibrated multisource PRF localization.

TIC 67300566: PROBABLE

Full bounded review COMPLETE under current paper section2.7. Historical screened status was not an admission. Catalogue novelty is separate; central seven-group coverage applies, see ../../catalogues/coverage-matrix.csv. No exhaustive priority claim.

1. **Raw repeated eclipses: pass.** 6 directly measured raw QLP SAP events in sectors[73, 86]. Representative raw-event plots and numeric windows inspected. A local linear baseline plus free trapezoid was fitted to quality-zero cadences. Predicted centers only guide windows. Flagged/uncovered windows are not clean non-detections. At most three spread QLP sectors used; no mandatory all-event/all-sector fitting.
2. **Timing: pass with limitations below.** 6 same-kind measured times give P=4.42341934165 +/-0.00002389186d, reference eclipse epoch BTJD3288.44495593; epoch kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Historical photometric cycle branch guides association, not a fixed Gaia period fit. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. SparseS21 TIC20176241 instead uses duration/2 conservative allowance. Zero/singular timing fits are excluded; their real raw detections remain evidence. This is not a blind all-alias search.
3. **Attribution: unresolved after performed check.** DecidingS59 image peak[7, 7] matches target pixel[7, 7]; target-deficit offset0.051pixel, light-deficit offset6.735arcsec; PSF total-light scaled residual0.272. Gaia identifiers/WCS validated in identity-check.json (zero pixel mismatch). Capable neighbors listed below; required eclipse is approximate Gaia-G flux budget and pixel fractional losses are blended, not intrinsic source eclipses.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut yields1x1/3x3/5x5 depths6.926/6.929/6.498ppt, 5 stacked events, versus selected-kind raw QLP median12.142ppt. Aperture dilution and mixed primary/secondary stacks may change depth. Reused numeric image and plots, cutout identity and source algorithm checked; same TESS photons test reduction robustness, not independent observing occasions.
5. **Gaia geometry: consistent within stated model limitations.** DR3189461074831319680; P=4.4238367396 +/-0.0002841869d, e=0.083592, omega=61.1479deg. Closest edge-on conjunction offset-0.147851d (-0.033421phase), full-SB1-covariance linear Gaia uncertainty0.180326d at measured epoch. Approximate central duration3.99h vs measured median1.51h permits noncentral eclipses. Mass function0.076596solar, assumed primary mass1.145, minimum

companion0.620solar. This is not a detailed binary fit or an arbitrary sigma veto; correlation convention and near-reference sensitivity recorded in ../gaia-geometry.json.

Deciding limitations: Real repeated raw dips; capable G12.84 neighbor18.26arcsec away lies0.84pixel from deficit versus0.05pixel target offset. Uncalibrated close-source localization prevents definitive attribution; completed review retains probable.

Next check: Resolved eclipse photometry or calibrated multisource PRF localization.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization; no missing bounded admission check.

Archived source: sanitized report text.

TIC 20176241: CONFIRMED

Full bounded review COMPLETE under current paper section2.7. Historical screened status was not an admission. Catalogue novelty is separate; central seven-group coverage applies, see ../../catalogues/coverage-matrix.csv. No exhaustive priority claim.

1. **Raw repeated eclipses: pass.** 3 directly measured raw QLP SAP events in sectors[21, 48]. Representative raw-event plots and numeric windows inspected. A local linear baseline plus free trapezoid was fitted to quality-zero cadences. Predicted centers only guide windows. Flagged/uncovered windows are not clean non-detections. At most three spread QLP sectors used; no mandatory all-event/all-sector fitting.
2. **Timing: pass with limitations below.** 3 same-kind measured times give P=13.51921255715 +/-0.00106281621d, reference eclipse epoch BTJD1890.22784388; epoch kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Historical photometric cycle branch guides association, not a fixed Gaia period fit. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. SparseS21 TIC20176241 instead uses duration/2 conservative allowance. Zero/singular timing fits are excluded; their real raw detections remain evidence. This is not a blind all-alias search.
3. **Attribution: pass at TESS image resolution with limitations below.** DecidingS48 image peak[8, 7] matches target pixel[8, 7]; target-deficit offset0.095pixel, light-deficit offset1.009arcsec; PSF total-light scaled residual0.045. Gaia identifiers/WCS validated in identity-check.json (zero pixel mismatch). Capable neighbors listed below; required eclipse is approximate Gaia-G flux budget and pixel fractional losses are blended, not intrinsic source eclipses.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut yields1x1/3x3/5x5 depths80.163/80.642/79.239ppt, 2 stacked events, versus selected-kind raw QLP median85.111ppt. Aperture dilution and mixed primary/secondary stacks may change depth. Reused numeric image and plots, cutout identity and source algorithm checked; same TESS photons test reduction robustness, not independent observing occasions.
5. **Gaia geometry: consistent within stated model limitations.** DR3819970107903053312; P=13.5172019155 +/-0.0032729947d, e=0.059889, omega=16.4528deg. Closest edge-on conjunction offset0.152987d (0.011318phase), full-SB1-covariance linear Gaia uncertainty0.321871d at measured epoch. Approximate central duration6.98h vs measured median3.89h permits noncentral eclipses. Mass function0.115116solar, assumed primary mass1.08, minimum companion0.720solar. This is

not a detailed binary fit or an arbitrary sigma veto; correlation convention and near-reference sensitivity recorded in ../gaia-geometry.json.

Deciding limitations: Two well-sampledS48 events and third clear sparseS21 recurrence test period across55cycles. S21 missing egress/sparse core gets duration/2 conservative timing allowance, not calibrated confidence. Current MAST query finds only21/48, no newer sector.

Next check: Optional precision characterization; no missing bounded admission check.

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization; no missing bounded admission check.

Archived source: sanitized report text.

TIC 387275908: CONFIRMED

Full bounded review COMPLETE under current paper section2.7. Historical screened status was not an admission. Catalogue novelty is separate; central seven-group coverage applies, see ../../catalogues/coverage-matrix.csv. No exhaustive priority claim.

1. **Raw repeated eclipses: pass.** 10 directly measured raw QLP SAP events in sectors[46, 87]. Representative raw-event plots and numeric windows inspected. A local linear baseline plus free trapezoid was fitted to quality-zero cadences. Predicted centers only guide windows. Flagged/uncovered windows are not clean non-detections. At most three spread QLP sectors used; no mandatory all-event/all-sector fitting.
2. **Timing: pass with limitations below.** 10 same-kind measured times give P=4.39055204155 +/-0.00001165698d, reference eclipse epoch BTJD2556.19633037; epoch kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Historical photometric cycle branch guides association, not a fixed Gaia period fit. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. SparseS21 TIC20176241 instead uses duration/2 conservative allowance. Zero/singular timing fits are excluded; their real raw detections remain evidence. This is not a blind all-alias search.
3. **Attribution: pass at TESS image resolution with limitations below.** DecidingS72 image peak[8, 8] matches target pixel[8, 8]; target-deficit offset0.097pixel, light-deficit offset6.110arcsec; PSF total-light scaled residual0.823. Gaia identifiers/WCS validated in identity-check.json (zero pixel mismatch). Capable neighbors listed below; required eclipse is approximate Gaia-G flux budget and pixel fractional losses are blended, not intrinsic source eclipses.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut yields1x1/3x3/5x5 depths7.102/7.464/6.359ppt, 6 stacked events, versus selected-kind raw QLP median8.059ppt. Aperture dilution and mixed primary/secondary stacks may change depth. Reused numeric image and plots, cutout identity and source algorithm checked; same TESS photons test reduction robustness, not independent observing occasions.
5. **Gaia geometry: consistent within stated model limitations.** DR3316613880557800601 6; P=4.3913179458 +/-0.0006353543d, e=0.075001, omega=354.8170deg. Closest edge-on conjunction offset-0.257200d (-0.058570phase), full-SB1-covariance linear Gaia uncertainty0.254946d at measured epoch. Approximate central duration6.45h vs measured median2.15h permits noncentral eclipses. Mass function0.058270solar, assumed primary mass1.17,

minimum companion0.558solar. This is not a detailed binary fit or an arbitrary sigma veto; correlation convention and near-reference sensitivity recorded in ../gaia-geometry.json.

Deciding limitations: Capable neighbors27.34 and36.11arcsec are spatially separated from deficit0.10pixel from target. High total-light PSF residual0.823 reflects crowding and is not used alone as attribution evidence. Gaia phase offset-0.059 has covariance uncertainty0.255d; duration can be noncentral.

Next check: Optional precision characterization; no missing bounded admission check.

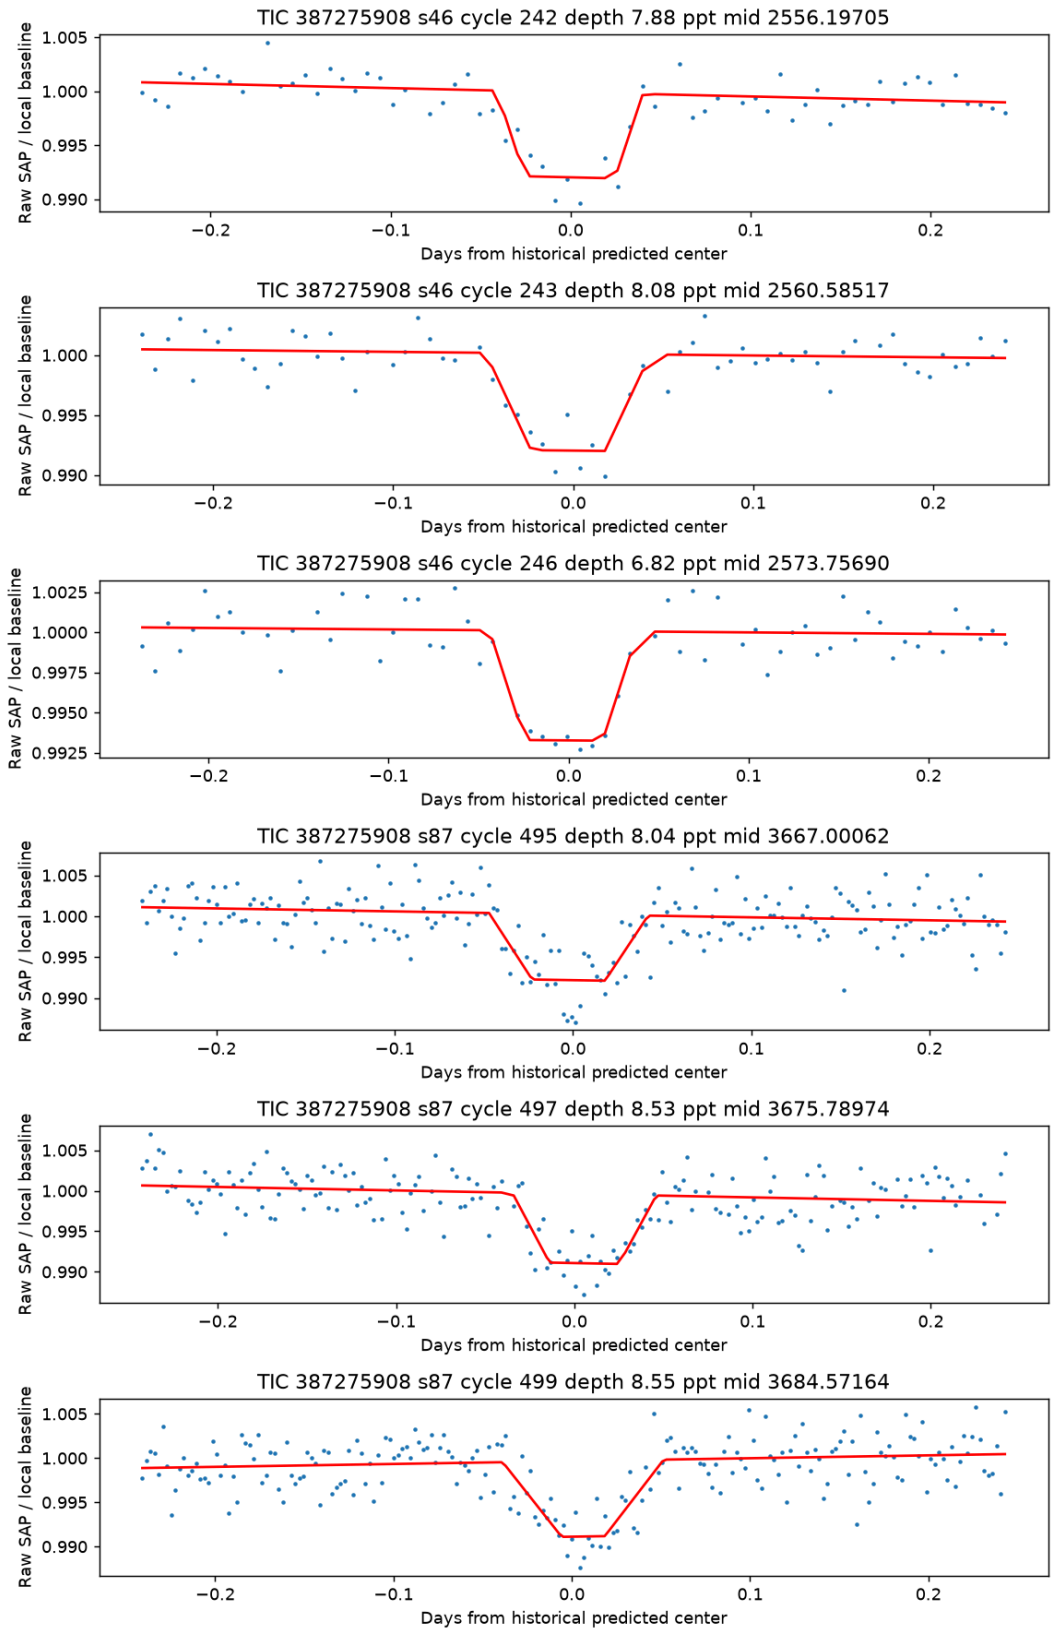
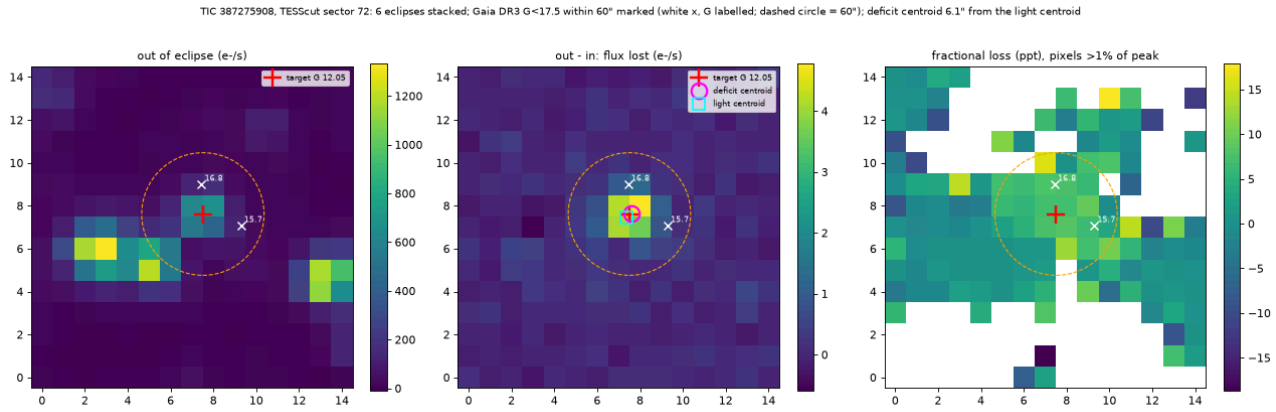
Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, historical/diff_s72.json, historical/diff_s72.png, historical/gaia.json; ../identity-check.json, ../gaia-geometry.json, ../helper-audit.md and ../SHA256SUMS.json. Original cutout: [local path omitted] QLP FITS and source paths with hashes retained in manifest. Difference events' JSON coordinates are predictions, never timing measurements. Interpretation uses bounded representative evidence rather than automatic historical screening.

Stable review key: R276. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R276; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.



R276; diff_s72.png. Target-pixel eclipse-deficit evidence; capable-neighbour and angular-resolution limitations remain in the full report.

Reserved and cumulative magnitude comparison. The second reserved sixty: At G = 11.5-12 (actual DR3 range 11.6648-11.9955), 29/30 are physically confirmed (96.7%; descriptive Wilson 95% interval 83.3-99.4%), 1 probable and 0 plausible; 30 new counted additions. At G = 12-12.5 (actual DR3 range 12.0036-12.4872), 26/30 are physically confirmed (86.7%; descriptive Wilson 95% interval 70.3-94.7%), 2 probable and 2 plausible; 28 new counted additions. Both rounds together: At G = 11.5-12 (actual DR3 range 11.6648-11.9955), 56/60 are physically confirmed (93.3%; descriptive Wilson 95% interval 84.1-97.4%), 4 probable and 0 plausible; 60 new counted additions. At G = 12-12.5 (actual DR3 range 12.0029-12.4879), 47/60 are physically confirmed (78.3%; descriptive Wilson 95% interval 66.4-86.9%), 10 probable and 3 plausible; 56 new counted additions. All 120 selected targets completed the bounded review and remain in their selected denominators. Known recoveries enter physical confirmation but add nothing; probable and plausible outcomes remain separate. The first-round results above are retained unchanged. These are descriptive remaining-screened candidate comparisons, not blind discovery yield, completeness or a causal magnitude effect. Wilson intervals are binomial model summaries despite finite historical strata; case mix, depletion, crowding, coverage and selection bookkeeping limit interpretation.

R277. TIC 336856559

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 336856559: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 13 distinct eclipse events in selected sectors[66, 103]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 13 same-kind midtimes give P=2.9097059074 ±0.0000018140d, reference eclipse epoch BTJD3098.6256467, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S103 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation4.441arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.937. Capable neighbours: Gaia 5969863533437354240: 45.91 arcsec, G9.994, required fractional eclipse0.170
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths99.668/54.231/27.297ppt, with 8 stacked events. QLP selected-kind fitted median124.260ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3596986352907839848, P=2.9097381651±0.0001997714d, e=0.101456, omega=131.0731deg. Closest edge-on conjunction offset-0.035368d (-0.012155phase), full-SB1-covariance linear propagated Gaia uncertainty0.195472d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.005336d (photometric period projection allowance0.001689d). The approximate central duration4.67h vs observed median3.37h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Strong aperture dilution: cutout1/3/5 depths99.7/54.2/27.3ppt; QLP sectors66/103 differ. Deficit0.211pixel from target, bright capable neighbor2.26pixels from deficit favors target. Depths are pipeline/aperture dependent, not intrinsic.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 146878534: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors[33, 87]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=8.9801438437 ±0.0000144498d, reference eclipse epoch BTJD2207.2276616, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S33 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation1.872arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.982. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths140.094/127.643/68.760ppt, with 3 stacked events. QLP selected-kind fitted median156.945ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3294612244435067865 6, P=8.9793296680±0.0004372996d, e=0.037114, omega=168.8437deg. Closest edge-on conjunction offset0.112481d (0.012527phase), full-SB1-covariance linear propagated Gaia uncertainty0.109595d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.051982d (photometric period projection allowance0.002919d). The approximate central duration5.91h vs observed median3.52h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Clean repeated sector33 eclipses150-174ppt; sector87 depths113-277ppt have changing steep baselines/noise. Real morphology and timing recur; apparent depth variability is not established astrophysically. Local-model timing systematics remain.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 123220126: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 12 distinct eclipse events in selected sectors[8, 62, 99]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=7.9647365731 ±0.0000076939d, reference eclipse epoch BTJD1519.0816018, kind: Deeper repeating eclipse; even half-period cycles. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S62 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.449arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.558. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths105.928/103.207/96.327ppt, with 6 stacked events. QLP selected-kind fitted median120.347ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR33824101617499474304, P=7.9648895117±0.0004901494d, e=0.017204, omega=144.7292deg. Closest edge-on conjunction offset-0.099881d (-0.012540phase), full-SB1-covariance linear propagated Gaia uncertainty0.050834d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.078164d (photometric period projection allowance0.001093d). The approximate central duration6.89h vs observed median4.58h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipse depths establish doubled orbital period. Even historical half-period cycles alone define deeper-eclipse ephemeris; historical cutout stack mixes kinds.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 42960522: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 20 distinct eclipse events in selected sectors[12, 99, 103]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 20 same-kind midtimes give P=2.5438060407 ±0.0000075069d, reference eclipse epoch BTJD1627.7359239, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S38 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation6.451arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.589. Capable neighbours: Gaia 5886342431117033728: 29.06 arcsec, G12.760, required fractional eclipse0.072; Gaia 5886336555601769088: 34.16 arcsec, G13.662, required fractional eclipse0.137; Gaia 5886336521242033536: 58.54 arcsec, G13.330, required fractional eclipse0.107; Gaia 5886342431117035648: 58.97 arcsec, G15.833, required fractional eclipse0.875; Gaia 5886336585650415360: 59.38 arcsec, G15.897, required fractional eclipse0.927
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths20.934/15.800/12.060ppt, with 10 stacked events. QLP selected-kind fitted median22.061ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35886336555601771392, P=2.5437447918±0.0002679482d, e=0.084019, omega=95.1819deg. Closest edge-on conjunction

offset0.042597d (0.016746phase), full-SB1-covariance linear propagated Gaia uncertainty0.140235d at the measured epoch. Near-Gaia-reference projected eclipse offset0.012769d (photometric period projection allowance0.003656d). The approximate central duration3.20h vs observed median3.27h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deficit0.307pixel from target; nearest capable neighbor1.55pixels from deficit. Spatial core supports target at TESS resolution; no calibrated centroid errors.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry / multi-source PRF localization

Archived source: sanitized report text.

TIC 374589618: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 23 distinct eclipse events in selected sectors[54, 81]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 9 same-kind midtimes give P=3.1662972967 ±0.0000098424d, reference eclipse epoch BTJD2778.4906828, kind: Deeper repeating eclipse; odd half-period cycles. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after check.** Historical S81 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation2.081arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.658. Capable neighbours: Gaia 1802168316060661376: 13.53 arcsec, G17.280, required fractional eclipse0.790; Gaia 1802168311763607936: 24.73 arcsec, G17.409, required fractional eclipse0.889; Gaia 1802168419139874048: 31.65 arcsec, G15.749, required fractional eclipse0.197; Gaia 1802165464202369664: 42.66 arcsec, G16.941, required fractional eclipse0.580; Gaia 1802168384780141824: 43.76 arcsec, G15.783, required fractional eclipse0.203; Gaia 1802168483562365568: 47.58 arcsec, G16.950, required fractional eclipse0.585; Gaia 1802168380483110784: 52.04 arcsec, G16.353, required fractional eclipse0.340; Gaia 1802168449202616960: 53.79 arcsec, G17.242, required fractional eclipse0.763
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths5.646/5.783/5.584ppt, with 14 stacked events. QLP selected-kind fitted median8.042ppt. This separately extracted cutout is an alternative reduction of the same TESS

photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3180216841913987328O, P=3.1662003845±0.0001950480d, e=0.028319, omega=52.2631deg. Closest edge-on conjunction offset0.107914d (0.034083phase), full-SB1-covariance linear propagated Gaia uncertainty0.120399d at the measured epoch. Near-Gaia-reference projected eclipse offset0.034746d (photometric period projection allowance0.007431d). The approximate central duration5.86h vs observed median1.60h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated shallow alternating eclipses are real; odd half-period cycles define deeper-eclipse timing. Deficit0.099pixel from target favors target, but capable neighbor13.5arcsec away is only0.67pixel from deficit and needs approximately79percent intrinsic eclipse. An undersampled sector54 fit can exaggerate depth (cycle2 fitted15.37ppt versus observed minimum about7-8ppt); that even-parity fit is excluded from the deeper odd-parity ephemeris. Shallow noisy difference image lacks calibrated localization; source attribution remains unresolved after bounded check.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 355885228: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors[24, 51, 78]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=12.2236227521 ±0.0000760471d, reference eclipse epoch BTJD1959.6132243, kind: Deeper repeating eclipse; even half-period cycles. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S24 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.151arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.060. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths21.673/20.791/20.470ppt, with 4 stacked events. QLP selected-kind fitted median26.934ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3121446711464822361 6, P=12.2241552395±0.0009737126d, e=0.003387, omega=37.0094deg. Closest edge-on conjunction offset-0.119695d (-0.009792phase), full-SB1-covariance linear propagated Gaia uncertainty0.140237d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.051537d (photometric period projection allowance0.009734d). The approximate central duration16.72h vs observed median10.74h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipses support doubled orbital period; three deeper even-half-period events include a sector24 same-kind repeat and sector78 recurrence. Historical cutout mixes kinds.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 169303527: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 10 distinct eclipse events in selected sectors[29, 69, 96]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 10 same-kind midtimes give P=5.4456847708 ±0.0000051113d, reference eclipse epoch BTJD2091.7221616, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S69 deficit peak[8, 8] vs target pixel[8, 7]; deficit-target separation1.330arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.165. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths131.025/128.228/120.717ppt, with 4 stacked events. QLP selected-kind fitted median132.330ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3232644655574370611 2, P=5.4456409811±0.0011930950d, e=0.165642, omega=93.6455deg. Closest edge-on conjunction offset0.022408d (0.004115phase), full-SB1-covariance linear propagated Gaia uncertainty0.264837d at the measured epoch. Near-Gaia-reference projected eclipse offset0.008702d (photometric period projection allowance0.001600d). The approximate central duration3.96h vs observed median3.17h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated eclipses show sector-dependent dilution/depth. No capable catalogued neighbor under approximate Gaia brightness screen.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 94541119: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[18, 44, 86]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=10.8933276600 ±0.0000227964d, reference eclipse epoch BTJD1797.8362059, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S18 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation4.970arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.063. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths109.574/108.335/107.029ppt, with 2 stacked events. QLP selected-kind fitted median109.533ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3170384999063309440, P=10.8955400325±0.0012192578d, e=0.271372, omega=337.0819deg. Closest edge-on conjunction offset-0.172802d (-0.015860phase), full-SB1-covariance linear propagated Gaia uncertainty0.156102d at the measured epoch. Near-Gaia-reference projected eclipse offset0.112595d (photometric period projection allowance0.002941d). The approximate central duration5.18h vs observed median4.53h permits noncentral geometry; this radius/minimum-mass estimate is not a

detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Five measured eclipses in sectors18/44/86 test period recurrence. No capable neighbor under approximate Gaia brightness screen; adopted depth is diluted.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 409935170: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 16 distinct eclipse events in selected sectors[13, 94, 103]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=8.7039814271 ±0.0000183962d, reference eclipse epoch BTJD1655.8339615, kind: Deeper repeating eclipse; even half-period cycles. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S94 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.121arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.184. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths129.075/126.963/119.540ppt, with 6 stacked events. QLP selected-kind fitted median135.909ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3642238084100151884 8, P=8.7056187340±0.0007330769d, e=0.021485, omega=165.0639deg. Closest edge-on conjunction offset-0.194825d (-0.022379phase), full-SB1-covariance linear propagated Gaia uncertainty0.106030d at the measured epoch. Near-Gaia-reference projected eclipse offset0.044222d (photometric period projection allowance0.002686d). The approximate central duration9.09h vs observed median7.60h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating depths within sectors establish doubled orbital period even though across-sector pooled depths overlap. Even half-period cycles alone define deeper-eclipse timing. Historical cutout mixes kinds.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 365864542: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 6 distinct eclipse events in selected sectors[15, 75, 83]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=13.3838603016 ±0.0000467881d, reference eclipse epoch BTJD1717.1172335, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S15 deficit peak[7, 8] vs target pixel[8, 8]; deficit-target separation2.180arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.482. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths257.577/247.957/195.923ppt, with 2 stacked events. QLP selected-kind fitted median277.197ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3216806596022264563 2, P=13.3807392140±0.0042403250d, e=0.382153, omega=217.8118deg. Closest edge-on conjunction offset0.192270d (0.014369phase), full-SB1-covariance linear propagated Gaia uncertainty0.445137d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.116718d (photometric period projection allowance0.004632d). The approximate central duration13.08h vs observed median9.73h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated isolated eclipses across three sectors; one singular center-covariance fit excluded. Aperture/sector depth differences retained; no intrinsic undiluted depth inferred.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 143375995: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 9 distinct eclipse events in selected sectors[7, 34, 88]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 9 same-kind midtimes give P=8.3596843935 ±0.0000123196d, reference eclipse epoch BTJD1492.9984843, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Unreliable fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S88 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.472arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.856. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths107.960/102.672/81.871ppt, with 4 stacked events. Historical event coordinates guide these stacks and are not newly measured midtimes. QLP selected-kind fitted median113.726ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3570040092735898316 8, P=8.3599586040±0.0006591686d, e=0.210170, omega=8.4067deg. Closest edge-on conjunction offset0.060141d (0.007194phase), full-SB1-covariance linear propagated Gaia uncertainty0.114884d at the measured epoch. Near-Gaia-reference projected eclipse offset0.096337d (photometric period projection allowance0.001626d). The approximate central duration8.53h vs observed median6.22h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep isolated eclipses recur across three sectors. Aperture depths vary with dilution; no capable catalogued neighbor within60arcsec under approximate Gaia G brightness test. PSF-scaled residual0.856 warns against interpreting this simple PSF fit quantitatively; deficit core is centered on target.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
7	0	1492.9980107	0.010417	112.398	usable; same-kind selection applies
7	1	1501.3580369	0.010417	110.266	usable; same-kind selection applies

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 122506579: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors[97]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=6.9345089138 ±0.0002217831d, reference eclipse epoch BTJD3939.4721930, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Unreliable fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S97 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation0.972arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.187. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths14.430/13.648/13.226ppt, with 7 stacked events. Historical event coordinates guide these stacks and are not newly measured midtimes. QLP selected-kind fitted median12.939ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3506714875020586624O, P=6.9335988748±0.0005002026d, e=0.004443, omega=329.5125deg. Closest edge-on conjunction offset0.607534d (0.087622phase), full-SB1-covariance linear propagated Gaia uncertainty0.259233d at the measured epoch. Near-Gaia-reference projected eclipse offset0.141594d (photometric period projection allowance0.113553d). The approximate central duration5.63h vs observed median2.26h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated shallow eclipses in sector97. Gaia orbit is nearly circular (e0.00444), so periastron/omega parameterization is weak; measured eclipse falls0.60753d (phase0.08762) from nearer nominal edge-on conjunction versus full-covariance linear allowance0.25923d. Other conjunction is2.87617d away. Near-reference projected offset0.14159d with photometric period projection allowance0.11355d; photometric P differs from Gaia by0.000910d versus Gaia error0.000500d. Retain mild orbit/timing tension, no arbitrary sigma veto or forced alias. Approximate central duration5.63h vs observed2.26h permits grazing/noncentral eclipse. Updated orbital solution would sharpen association.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Archived source: sanitized report text.

TIC 201598744: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 14 distinct eclipse events in selected sectors[93, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 14 same-kind midtimes give P=3.4086667035 ±0.0000083995d, reference eclipse epoch BTJD3830.7318892, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Unreliable fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S93 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation7.215arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.803. Capable neighbours: Gaia 6633731921030220032: 37.11 arcsec, G15.886, required fractional eclipse0.468; Gaia 6633638045927526528: 37.76 arcsec, G16.525, required fractional eclipse0.833; Gaia 6633684985627605248: 46.68 arcsec, G13.068, required fractional eclipse0.046; Gaia 6633684985627605376: 48.13 arcsec, G13.843, required fractional eclipse0.081; Gaia 6633638118945259264: 48.84 arcsec, G16.471, required fractional eclipse0.793; Gaia 6633731955389963776: 53.75 arcsec, G13.807, required fractional eclipse0.079
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths12.147/10.609/8.018ppt, with 8 stacked events. Historical event coordinates guide these stacks and are not newly measured midtimes. QLP selected-kind fitted median12.606ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3663373188237256857 6, P=3.4088296693±0.0003292291d, e=0.056446, omega=38.6510deg. Closest edge-on conjunction offset-0.084458d (-0.024776phase), full-SB1-covariance linear propagated Gaia uncertainty0.308497d at the measured epoch. Near-Gaia-reference projected eclipse offset0.080138d (photometric period projection allowance0.008483d). The approximate central duration3.94h vs observed median1.96h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Raw shallow eclipses recur in sectors93/104. Strong aperture dilution:1x1/3x3/5x5 depths12.15/10.61/8.02ppt. Deficit0.344pixel from target and closest capable catalogued neighbor1.63pixels from deficit favor target at TESS resolution. PSF-scaled residual0.803 is not a calibrated localization uncertainty.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

TIC 267094867: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 13 distinct eclipse events in selected sectors[1, 67, 96]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 12 same-kind midtimes give P=3.4708302926 ±0.0000031344d, reference eclipse epoch BTJD1345.8329151, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Unreliable fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S66 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.558arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.036. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths67.600/68.139/67.682ppt, with 8 stacked events. Historical event coordinates guide these stacks and are not newly measured midtimes. QLP selected-kind fitted median65.115ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3463989931929362816O, P=3.4710058980±0.0001561795d, e=0.015578, omega=37.0096deg. Closest edge-on conjunction offset-0.037602d (-0.010833phase), full-SB1-covariance linear propagated Gaia uncertainty0.038192d at the measured epoch. Near-Gaia-reference projected eclipse offset0.010865d (photometric period projection allowance0.000865d). The approximate central

duration6.12h vs observed median4.02h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep eclipses recur in sectors1/67/96; sector-dependent depths and shapes retained. Singular sector67 cycle520 fit excluded from timing. No capable catalogued neighbor in approximate brightness test.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

R291. TIC 156985493

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional short-cadence resolved photometry and revised spectroscopy

Archived source: sanitized report text.

TIC156985493: CONFIRMED

Full bounded review: COMPLETE. Physical classification is separate from central catalogue novelty. Root scientific acceptance is required before integration.

1. **Raw repeats: pass.** Two actual unflagged narrow sector22 SAP eclipses and two sector49 eclipses are measured. The generic25-point fit gate missed short events at30minute cadence; its empty result remains pipeline_measurements.json. Independent helper examined actual SAP samples and plots, measuring quadratic trough centers from3-4 samples in sector22 and free Gaussian plus linear baseline centers in sector49. Historical predicted epochs drifted and were not used as measured timings. See helper/independent_raw.png and helper/156-alias-windows.png.
2. **Measured same-kind timing and aliases: pass.** Four measured centers at cycles0,1,74,76 give P=9.9472023084 +/-0.0001041208d and selected-eclipse epoch BTJD1908.15679456. Kind: Selected repeating narrow eclipse; primary by convention, relative secondary depth unestablished. Sector22 adjacent spacing9.94631d and sector49 two-cycle spacing19.89509d test recurrence across the gap. Half-period alternatives at BTJD2649.223 and2659.171 have15/17 and14/17 unflagged cadences and minima0.99764/0.99915 of baseline, excluding comparable12ppt intermediate eclipses. A separate shallower secondary remains possible. This is a bounded alias check, not exhaustive all-period search. Error meaning: Weighted linear fit to two sparse quadratic trough centers at sector22 and two free Gaussian plus linear centers at sector49. Inputs max(formal covariance where available, half cadence); sector22 half cadence is a coarse allowance. Covariance inflated if reduced chi square exceeds one. Mixed-model, cadence-smearing, baseline and pipeline systematics are not calibrated, not total uncertainty or coverage.
3. **Target attribution: pass at TESS resolution.** Newly fetched sector22 TESScut difference has positive-deficit5x5 centroid(7.7458,7.7067) vs WCS target(7.797,7.723), separation0.054pixel. No calibrated centroid uncertainty. Successful current MAST TIC60arcsec cone finds two Gaia-linked neighbors at39.92/54.44arcsec, G20.231/20.323. Producing11ppt target loss would require approximately26/28 times their entire Gaia G flux, so neither is capable under that approximate color/aperture brightness proxy. This is not proof against uncatalogued unresolved companions. Receipt helper/156-tic-cone.json; cutout image helper/156-cutout-difference.png.
4. **Alternative reduction: pass.** Independently extracted TESScut pixel-aperture flux reproduces both sector22 dips. Event1 1x1/3x3/5x5 average depths5.93/6.66/4.95ppt; event2 9.39/5.42/2.93ppt. Apertures center on brightest pixel(8,8), without background subtraction, in-event +/-0.027d and out-of-event0.065-0.17d. These smeared average depths differ from QLP trough/model depths, as expected from cadence, extraction and dilution. Same TESS photons, not independent observations. Source FITS, script and hash in helper/156-independent.json and helper/tesscut156.

5. **Full NSS Gaia geometry: pass with limitations.** DR34000328107088372352; GaiaP=9.9466027631+/-0.0012787442d, e=0.151498, omega=132.2616deg. Closest edge-on conjunction offset0.101824d (0.010237phase), full SB1 covariance linear allowance0.191661d at measured epoch. Mass function0.042525solar masses, assumed primary1.090, minimum companion0.469. Approximate central duration5.46h vs observed approximate sector22 cutout FWHM1.2h allows grazing/noncentral geometry. This is descriptive edge-on/minimum-mass comparison, not detailed binary modeling; no arbitrary sigma veto. Full inputs/covariance assumptions in gaia-geometry.json.

Queue-preparation QLP availability product list (targets-selected.json, hashed in helper/156-checks.json) contains sectors22 and49, both investigated. This reuses the campaign product list rather than asserting an independent fresh helper query. Sector49 previously flagged predicted windows were not clean nulls; shifted actual eclipse windows reveal repeats. No replacement or denominator exclusion.

Limitations: Narrow eclipses at30minute cadence in sector22 have only3-4 trough samples. Mixed quadratic/Gaussian timing model and cadence floors are descriptive allowances, not total uncertainty. Sector49 cycle75 and sector22 half-period midpoint are flagged/gaps, not clean nulls; other sector49 half-period windows have usable flat samples. Same photons, aperture dilution and uncalibrated centroid uncertainty remain. Approximate1.2h observed FWHM differs from modeled central duration; grazing geometry possible, no detailed binary fit.

Next check: Optional short-cadence resolved photometry and revised spectroscopy for sharper eclipse morphology/geometry; no missing bounded admission check.

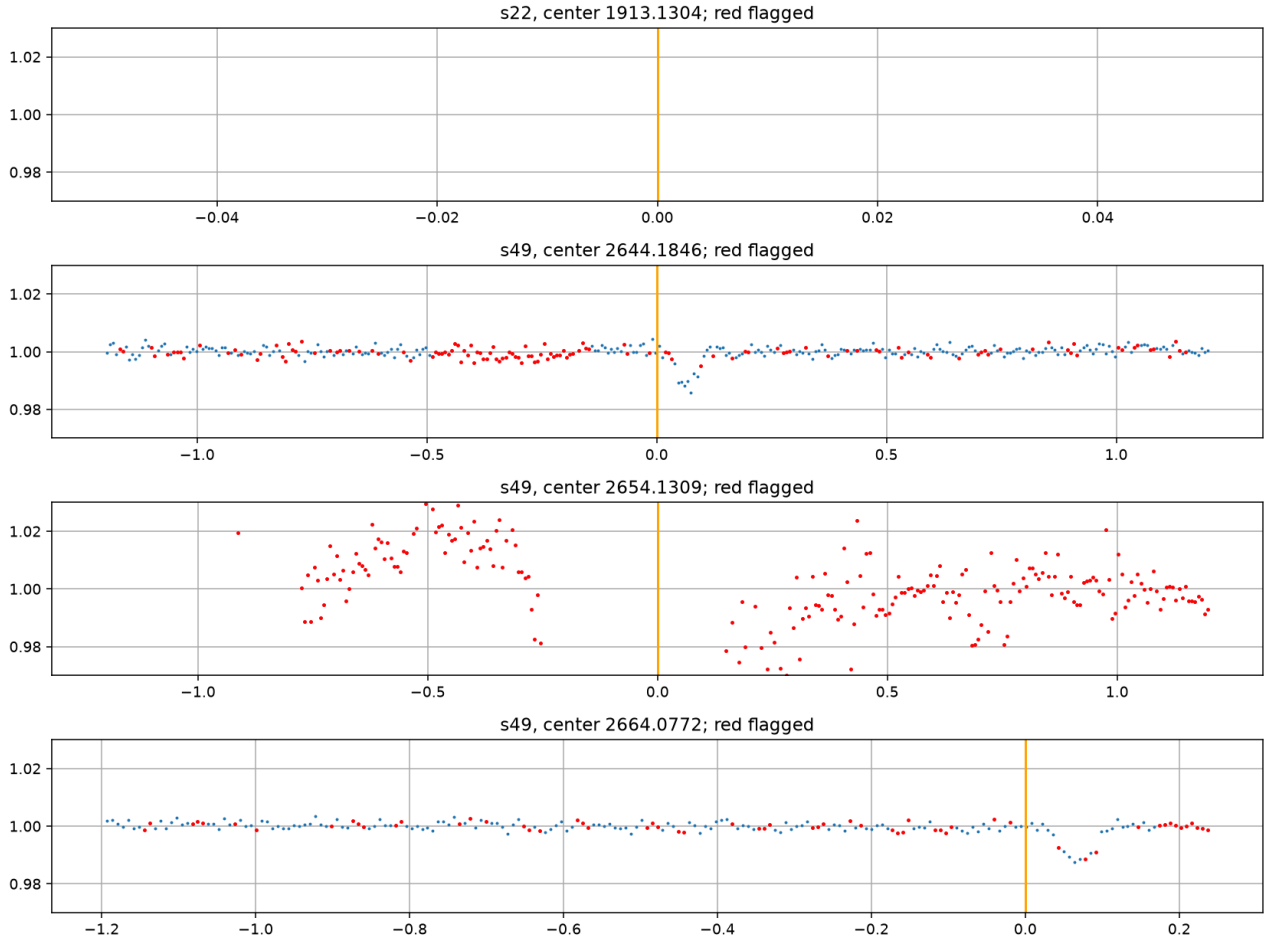
Catalogue novelty is supplied separately by ../../catalogues/coverage-matrix.csv. This physical report does not claim exhaustive literature priority.

Sector	Cycle	Measured midpoint BTJD	Timing input d	Depth ppt	Method
22	0	1908.15727703	0.01041675	11.524	quadratic through 3-4 trough samples, cadence/2 allowance
22	1	1918.10359176	0.01041675	11.950	quadratic through 3-4 trough samples, cadence/2 allowance
49	74	2644.24941621	0.00347220	13.284	Gaussian plus linear baseline, unflagged SAP, sigma max(formal, cadence/2)
49	76	2664.14451057	0.00347220	12.603	Gaussian plus linear baseline, unflagged SAP, sigma max(formal, cadence/2)

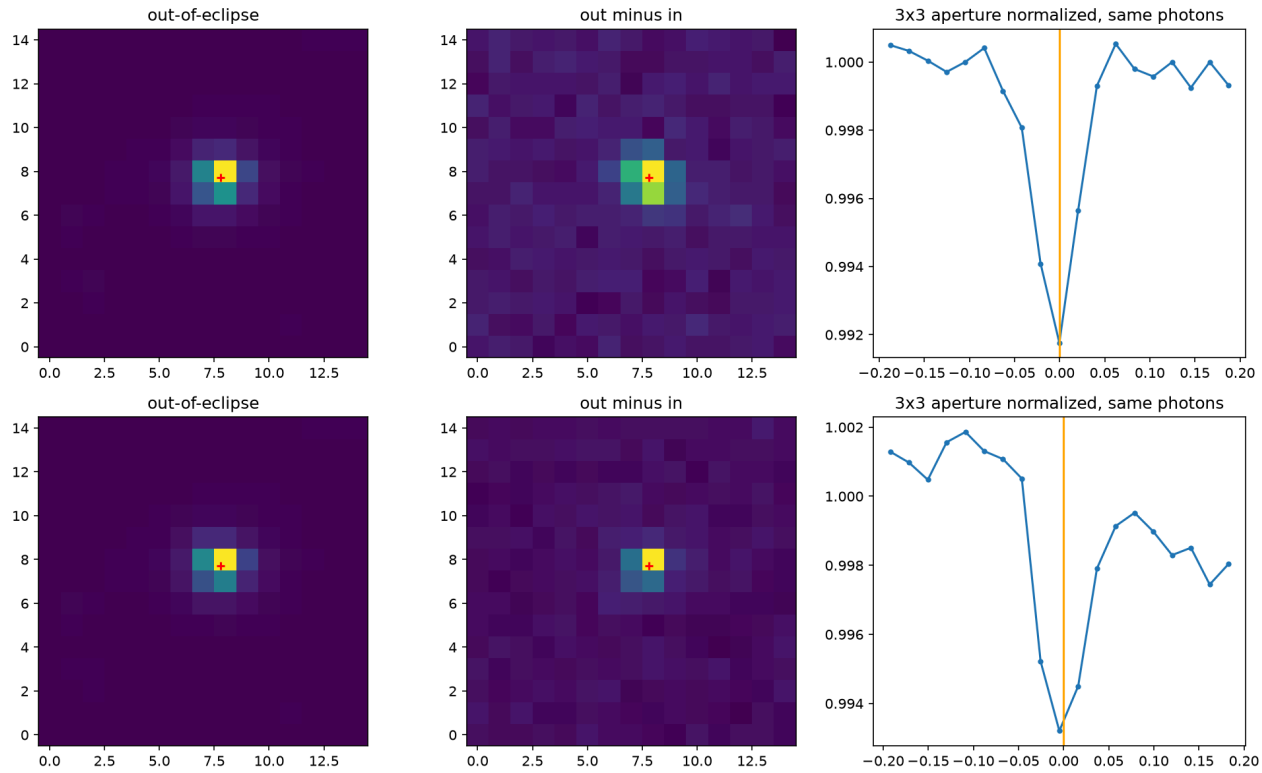
Evidence (original source layout; use the public evidence links below for exported locations): measurements.json; pipeline_measurements.json; ../helper/156-independent.json; ../helper/156-independent.py; ../helper/156-sector49.py; ../helper/156-alias-windows.png; ../helper/156-cutout-difference.png; ../helper/156-tic-cone.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Shared QLP source hashes in ../download-receipts.json. Public identity boundary respected.

Stable review key: R291. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.

Editorial update after review: the coordinator accepted this completed review for integration. The original pre-acceptance wording above records the lead handoff. Direct deciding evidence: raw sector-49 eclipse and coverage windows, sector-22 eclipse extractions and deficit images, and independent measurements. Orange guide lines are predictions, not measured timing points; flagged or empty windows are not clean nulls.



R291; 156-alias-windows.png. Actual sector-49 raw-flux windows include two shifted eclipses and empty or flagged intermediate windows. Orange predicted lines are not measured timings; the report gives measured centers and alias qualifications.



R291; 156-cutout-difference.png. Sector-22 actual-event cutout and pixel-aperture alternative reduction; centroid and angular-resolution qualifications remain in the full report.

R292. TIC 189664666

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 189664666: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors[91]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=3.4725104030 ±0.0005545785d, reference eclipse epoch BTJD3778.6307516, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Unreliable fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S91 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation1.658arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.056. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths43.381/43.134/42.826ppt, with 2 stacked events. Historical event coordinates guide these stacks and are not newly measured midtimes. QLP selected-kind fitted median43.073ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3630082350835706867 2, P=3.4727173222±0.0003480687d, e=0.061438, omega=290.4505deg. Closest edge-on conjunction offset0.002382d (0.000686phase), full-SB1-covariance linear propagated Gaia uncertainty0.359401d at the measured epoch. Near-Gaia-reference projected eclipse offset0.204335d (photometric period projection allowance0.541269d). The approximate central

duration5.39h vs observed median5.01h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four real raw eclipses in sector91; discontinuous egress/baseline ramp in cycle5 makes its trapezoid center unreliable and excluded. Three other same-kind timings fit the period. No capable catalogued neighbor in approximate brightness test. Timing baseline is only14d, not precision long-baseline characterization.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

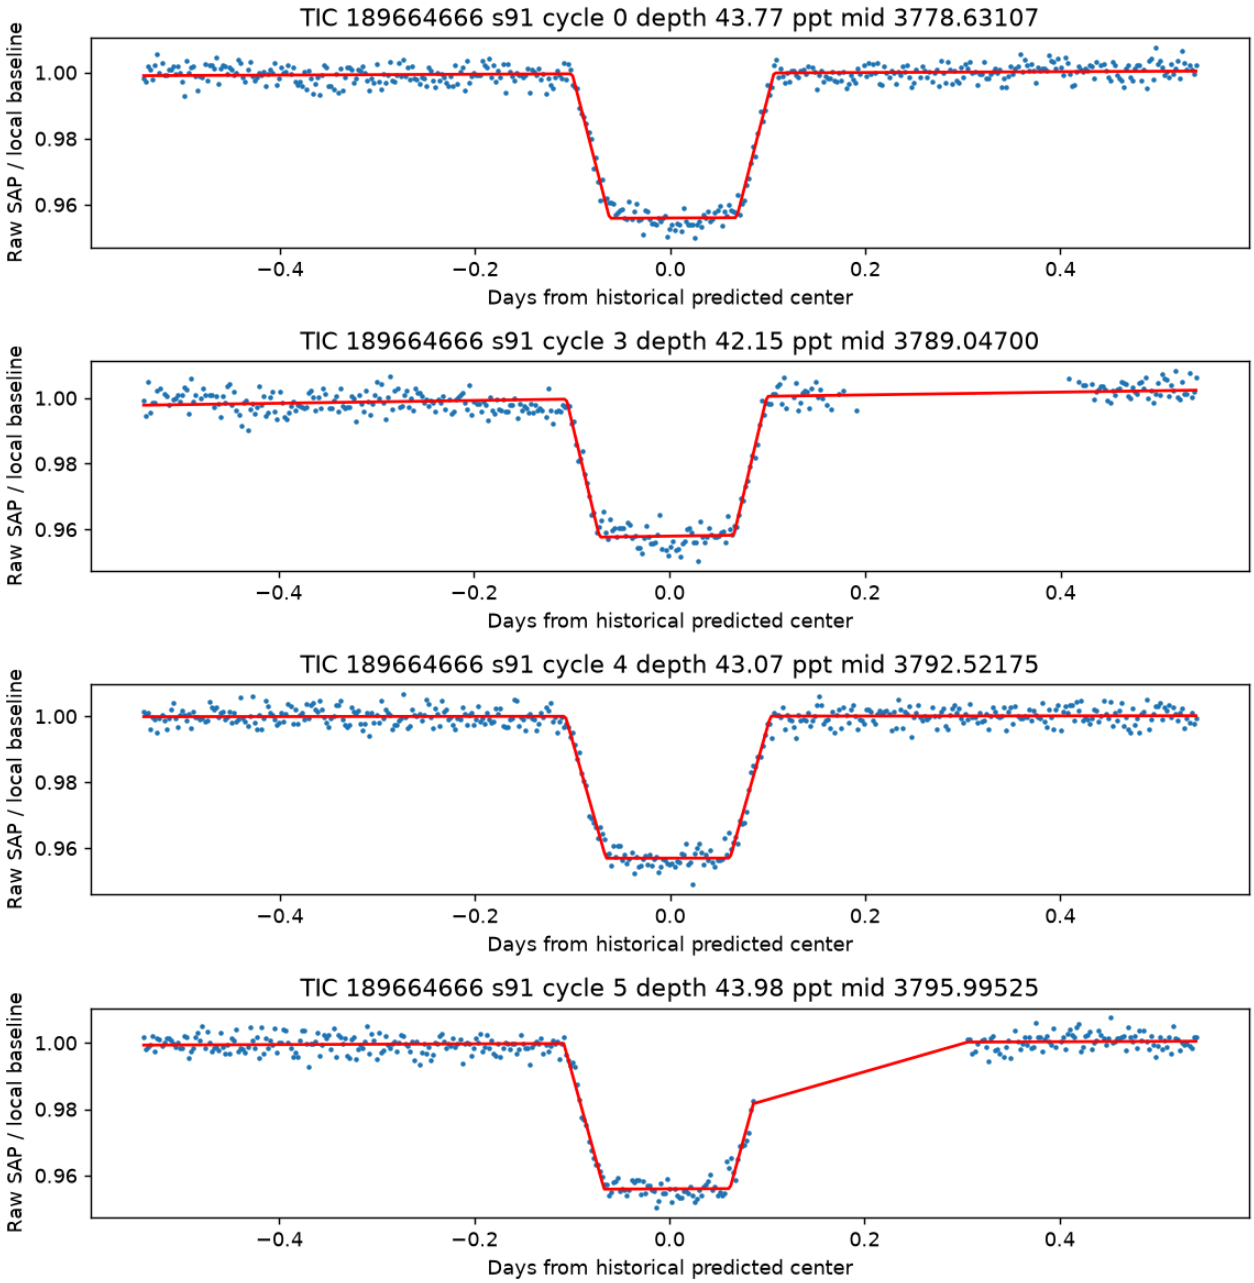
Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

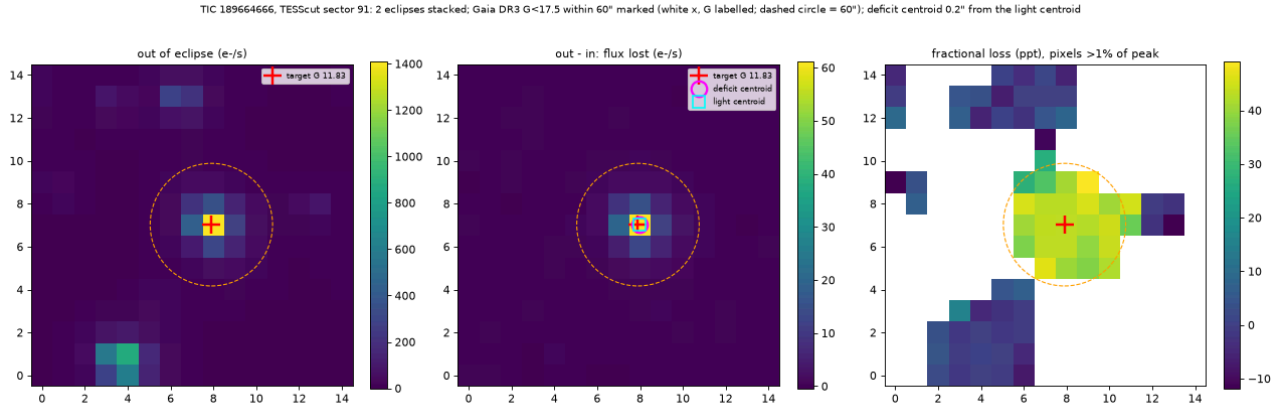
Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
91	0	3778.6310718	0.001157	43.774	usable; same-kind selection applies
91	3	3789.0470020	0.001157	42.146	usable; same-kind selection applies
91	4	3792.5217538	0.001157	43.073	usable; same-kind selection applies
91	5	3795.9952516	0.001157	43.976	excluded unreliable timing fit

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, shared-qlp QLP FITS; historical/diff_s91.json, historical/diff_s91.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R292. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R292; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.



R292; diff_s91.png. Target-pixel eclipse-deficit evidence; capable-neighbour and angular-resolution limitations remain in the full report.

Archived source: sanitized report text.

TIC 309308701: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors[73, 86]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=18.3848616420 ±0.0001132702d, reference eclipse epoch BTJD3291.8509571, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Unreliable fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S73 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.247arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.312. Capable neighbours: Gaia 261872853348447872: 27.98 arcsec, G15.831, required fractional eclipse0.708
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths20.421/18.408/17.309ppt, with 2 stacked events. Historical event coordinates guide these stacks and are not newly measured midtimes. QLP selected-kind fitted median20.689ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3261872780332852736, P=18.3808647997±0.0048918530d, e=0.311976, omega=136.7904deg. Closest edge-on conjunction offset0.655409d (0.035657phase), full-SB1-covariance linear propagated Gaia uncertainty0.842000d at the measured epoch. Near-Gaia-reference projected eclipse offset0.023907d (photometric period projection allowance0.017897d). The approximate central

duration11.27h vs observed median5.50h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four shallow isolated eclipses in sectors73/86, including adjacent-cycle pairs, test recurrence. Target-deficit0.155pixel vs nearest capable neighbor1.50pixels favors target; no calibrated centroid errors. Gaia nominal conjunction offset0.6554d but full-covariance linear allowance0.8420d and near-reference offset0.0239d support compatible geometry.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R294. TIC 141811748

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 141811748: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors[1, 37, 98]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=6.8389313923 ±0.0000094980d, reference eclipse epoch BTJD1334.0304484, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Unreliable fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S97 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation3.935arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.218. Capable neighbours: Gaia 5260245291514395136: 38.08 arcsec, G14.242, required fractional eclipse0.394
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths37.325/34.581/32.925ppt, with 7 stacked events. Historical event coordinates guide these stacks and are not newly measured midtimes. QLP selected-kind fitted median31.682ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3526024560075204 3648, P=6.8386133503±0.0007182882d, e=0.029587, omega=203.5107deg. Closest edge-on conjunction offset0.001233d (0.000180phase), full-SB1-covariance linear propagated Gaia uncertainty0.123473d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.042657d (photometric period projection allowance0.001311d). The approximate central duration8.07h vs observed median4.78h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated eclipses across three sectors; sector/aperture-dependent dilution retained. Target-deficit0.187pixel vs closest capable neighbor1.67pixels favors target; no calibrated centroid errors. Sector37 actual adjacent cycles144/145/146 show raw core depths38.52/37.30/37.68ppt (11/11/12 in-event cadences); cycle145 fails fit side-window threshold but tests recurrence. Missing even sector98 cycles have no raw coverage. Sparse sector1 cycles0/1/2 also recur. Thus apparent alternating-sector98 pattern is coverage, not doubled period; see coverage-alias.json.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R295. TIC 5781196

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 5781196: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 2 distinct eclipse events in selected sectors[36, 99]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 2 same-kind midtimes give P=11.0017719770 ±0.0000228750d, reference eclipse epoch BTJD2289.0187466, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Unreliable fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S89 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation5.093arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.441. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths215.498/201.534/157.504ppt, with 3 stacked events. Historical event coordinates guide these stacks and are not newly measured midtimes. QLP selected-kind fitted median202.989ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3543584746895666856, P=11.0028295172±0.0015099322d, e=0.570356, omega=115.9229deg. Closest edge-on conjunction offset-0.189598d (-0.017232phase), full-SB1-covariance linear propagated Gaia uncertainty0.272145d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.006644d (photometric period projection allowance0.003957d). The approximate central

duration2.79h vs observed median2.30h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Two precisely fitted deep events in sectors36/99 are supplemented by helper raw sector89 THREE adjacent repeated eclipses near BTJD3719/3730/3741 separated by11.0018d. Those actual raw repeats test long-baseline integer-cycle aliases; they are not predicted centers used as measured timings. Strong aperture/sector dilution differences remain; no capable catalogued neighbor within60arcsec.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

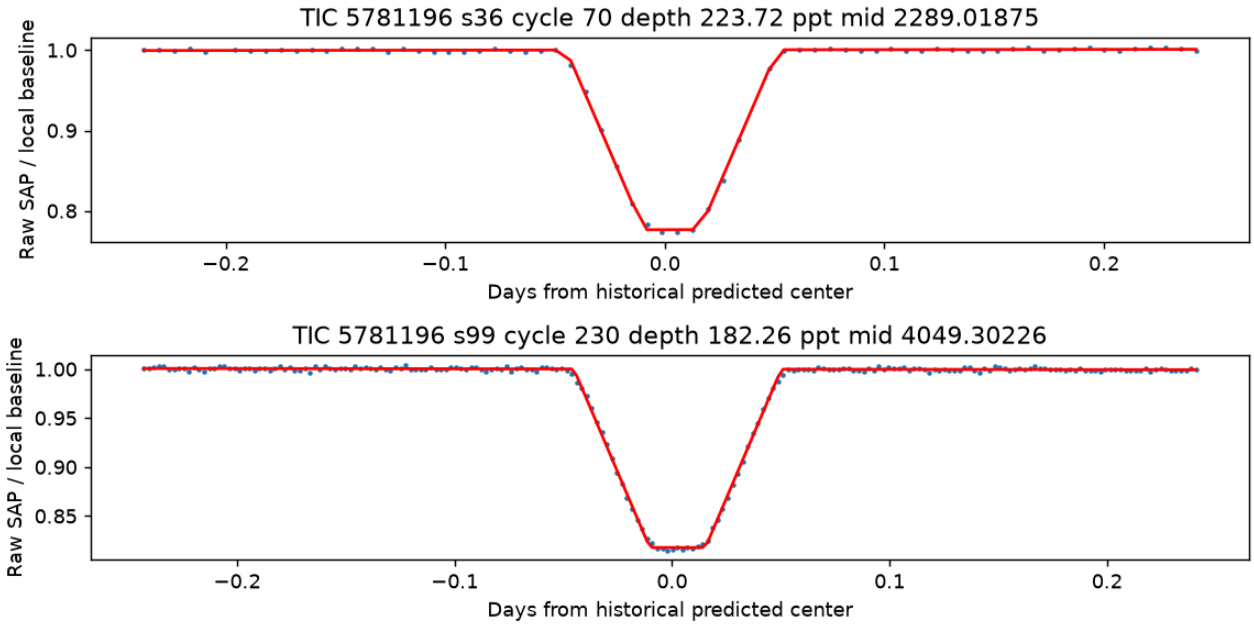
Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

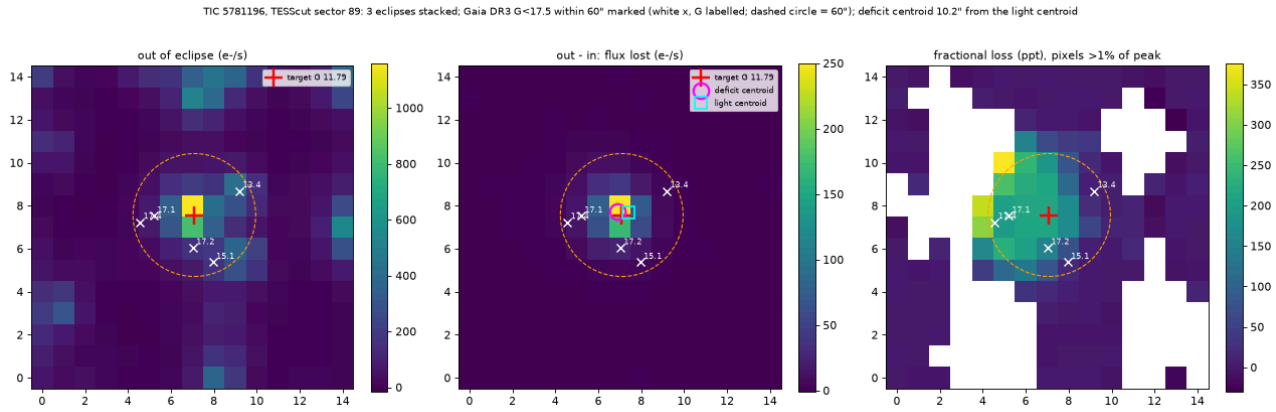
Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
36	70	2289.0187466	0.003472	223.722	usable; same-kind selection applies
99	230	4049.3022629	0.001157	182.256	usable; same-kind selection applies

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, shared-qlp QLP FITS; historical/diff_s89.json, historical/diff_s89.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R295. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R295; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.



R295; diff_s89.png. Target-pixel eclipse-deficit evidence; capable-neighbour and angular-resolution limitations remain in the full report.

R296. TIC 370329832

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 370329832: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[38, 90]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=9.4634975241 ±0.0000170165d, reference eclipse epoch BTJD2344.0833839, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Unreliable fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S63 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.495arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.582. Capable neighbours: Gaia 5219338717319681536: 35.44 arcsec, G15.976, required fractional eclipse0.980; Gaia 5219338511161254272: 38.70 arcsec, G12.998, required fractional eclipse0.084; Gaia 5219340263507912448: 47.07 arcsec, G15.901, required fractional eclipse0.916; Gaia 5219338751679414528: 59.13 arcsec, G15.279, required fractional eclipse0.527
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths22.301/21.219/17.450ppt, with 3 stacked events. Historical event coordinates guide these stacks and are not newly measured midtimes. QLP selected-kind fitted median24.210ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3521933871301999936O, P=9.4629554699±0.0011615825d, e=0.014692, omega=346.6392deg. Closest edge-on conjunction

offset0.099963d (0.010564phase), full-SB1-covariance linear propagated Gaia uncertainty0.214371d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.012242d (photometric period projection allowance0.003522d). The approximate central duration8.06h vs observed median3.32h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Five measured shallow eclipses include adjacent repeated pairs in sectors38/90, testing period recurrence. Target-deficit0.071pixel vs closest capable neighbor1.86pixels favors target. Sector63 alternative extraction depths22.30/21.22/17.45ppt show dilution. No calibrated localization error.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 379550793: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 19 distinct eclipse events in selected sectors[64, 101]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 19 same-kind midtimes give P=2.4798111572 +/-0.0000014767d, reference eclipse epoch BTJD3041.9007652, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S38 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation6.620arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.700. Capable neighbours: Gaia 6058502724870374912: 15.61 arcsec, G16.097, required fractional eclipse0.529; Gaia 6058502793589851136: 20.31 arcsec, G15.796, required fractional eclipse0.404; Gaia 6058502724870373888: 21.42 arcsec, G13.912, required fractional eclipse0.081; Gaia 6058502724870375552: 27.27 arcsec, G14.352, required fractional eclipse0.115; Gaia 6058502724870373760: 29.18 arcsec, G16.482, required fractional eclipse0.749; Gaia 6058502754891546752: 36.05 arcsec, G16.282, required fractional eclipse0.625; Gaia 6057752102023464064: 38.96 arcsec, G16.156, required fractional eclipse0.558; Gaia 6058502793589852544: 40.20 arcsec, G16.063, required fractional eclipse0.513; Gaia 6058502690510531712: 42.43 arcsec, G16.447, required fractional eclipse0.726; Gaia 6057752136383209344: 42.52 arcsec, G15.938, required fractional eclipse0.458; Gaia 6058502690510531456: 45.24 arcsec, G15.898, required fractional eclipse0.442; Gaia 6058502759230114816: 46.85 arcsec, G14.905, required fractional eclipse0.184; Gaia

6057752136383211136: 48.56 arcsec, G15.402, required fractional eclipse0.284; Gaia 6058502793555875456: 51.23 arcsec, G16.436, required fractional eclipse0.718; Gaia 6058502793589748352: 51.39 arcsec, G14.227, required fractional eclipse0.104; Gaia 6058502621791051776: 53.01 arcsec, G13.381, required fractional eclipse0.054; Gaia 6058502793589748992: 54.98 arcsec, G16.251, required fractional eclipse0.608; Gaia 6058502621791051904: 55.79 arcsec, G15.214, required fractional eclipse0.241; Gaia 6057752136383212800: 56.20 arcsec, G14.549, required fractional eclipse0.136

4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths12.036/10.485/7.514ppt, with 11 stacked events. QLP selected-kind fitted median11.453ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR36058502724870374272, P=2.4797362150+/-0.0001521287d, e=0.018215, omega=160.3186deg. Closest edge-on conjunction offset0.076701d (0.030931phase), full-SB1-covariance linear propagated Gaia uncertainty0.172965d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.003488d (photometric period projection allowance0.001580d). The approximate central duration4.42h vs observed median1.79h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Crowded field: deficit0.315pixel from target; closest capable neighbor0.856pixel from deficit (G13.91,21.4arcsec). Peak/core favors target, with no calibrated centroid errors; aperture depths12.04/10.48/7.51ppt and sector depths differ through dilution. Intrinsic neighbor eclipse requirements are not directly compared with blended pixel losses.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 161823655: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[15, 51, 85]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=11.6070592589 +/-0.0000733037d, reference eclipse epoch BTJD1713.7278770, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S16 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.147arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.153. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths64.990/64.779/63.789ppt, with 2 stacked events. QLP selected-kind fitted median67.139ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3162598549340050764 8, P=11.6063345473+/-0.0017583299d, e=0.067125, omega=257.8654deg. Closest edge-on conjunction offset0.085945d (0.007405phase), full-SB1-covariance linear propagated Gaia uncertainty0.256699d at the measured epoch. Near-Gaia-reference projected eclipse offset0.003328d (photometric period projection allowance0.008357d). The approximate central duration7.97h vs observed median7.18h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Five measured events over three sectors, including adjacent same-kind repeats. Raw sector85 has changing baselines but clear narrow core; depth variation alone is not established astrophysically. No capable neighbor under approximate Gaia flux-budget screen.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 341118777: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[13, 101, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=6.8474689646 +/-0.0000169388d, reference eclipse epoch BTJD1665.0429604, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S67 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation0.609arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.056. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths112.012/112.820/109.723ppt, with 4 stacked events. QLP selected-kind fitted median95.174ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3645427248070527884 8, P=6.8477864674+/-0.0007556392d, e=0.070259, omega=102.3940deg. Closest edge-on conjunction offset0.013863d (0.002024phase), full-SB1-covariance linear propagated Gaia uncertainty0.171384d at the measured epoch. Near-Gaia-reference projected eclipse offset0.072919d (photometric period projection allowance0.003151d). The approximate central duration4.74h vs observed median3.81h permits noncentral geometry; this radius/minimum-mass estimate is not a

detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated events in sectors13/101. Sector104 cycle371 singular center covariance is excluded from timing; its real partial/noisy morphology is retained as documentation. No capable neighbor under approximate flux-budget screen.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 21952826: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors[62, 99]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=9.7685847110 +/-0.0000106665d, reference eclipse epoch BTJD2995.8445787, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S35 deficit peak[8, 8] vs target pixel[8, 7]; deficit-target separation7.214arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.137. Capable neighbours: Gaia 5659918043089101184: 40.76 arcsec, G15.240, required fractional eclipse0.520; Gaia 5659918008729365120: 55.61 arcsec, G15.689, required fractional eclipse0.774
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths24.848/24.899/23.814ppt, with 2 stacked events. QLP selected-kind fitted median25.067ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3565992099802659936, P=9.7676391567+/-0.0023223683d, e=0.018212, omega=79.9643deg. Closest edge-on conjunction offset0.238592d (0.024427phase), full-SB1-covariance linear propagated Gaia uncertainty0.691423d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.013871d (photometric period projection allowance0.002848d). The approximate central duration4.73h vs observed median2.44h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four measured repeats, with consecutive events in sector62. Deficit0.344pixel from target; nearest capable neighbor2.08pixels from deficit. Sector-dependent depth may reflect aperture dilution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 308986181: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[9, 89, 100]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=5.4022635217 +/-0.0000095649d, reference eclipse epoch BTJD1548.8549832, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S89 deficit peak[7, 8] vs target pixel[7, 7]; deficit-target separation3.686arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.246. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths32.580/32.803/31.486ppt, with 4 stacked events. QLP selected-kind fitted median31.450ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3565980650708206720O, P=5.4023202539+/-0.0006108168d, e=0.039226, omega=160.9576deg. Closest edge-on conjunction offset-0.103122d (-0.019088phase), full-SB1-covariance linear propagated Gaia uncertainty0.138927d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.090925d (photometric period projection allowance0.002056d). The approximate central duration5.81h vs observed median4.85h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Eleven clear measured eclipses in three widely separated sectors. No capable neighbor under approximate Gaia flux-budget screen; target deficit0.176pixel from target.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

TIC 262082690: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 4 distinct eclipse events in selected sectors[99, 102]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=8.9388713010 +/-0.0002620764d, reference eclipse epoch BTJD4046.7449950, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S38 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation0.127arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.770. Capable neighbours: Gaia 5824713631846649600: 15.10 arcsec, G14.737, required fractional eclipse0.238; Gaia 5824713631839658496: 18.02 arcsec, G13.778, required fractional eclipse0.108; Gaia 5824713533092293376: 25.66 arcsec, G12.694, required fractional eclipse0.050; Gaia 5824713498732554368: 50.69 arcsec, G15.928, required fractional eclipse0.679; Gaia 5824713464372814080: 50.83 arcsec, G15.472, required fractional eclipse0.452; Gaia 5824713567452030208: 51.09 arcsec, G13.914, required fractional eclipse0.120; Gaia 5824713842341027456: 51.58 arcsec, G15.649, required fractional eclipse0.529; Gaia 5824713567452030080: 54.31 arcsec, G13.998, required fractional eclipse0.129; Gaia 5824713567452031488: 56.02 arcsec, G14.401, required fractional eclipse0.179
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths14.101/12.255/9.816ppt, with 3 stacked events. QLP selected-kind fitted median16.691ppt. This separately extracted cutout is an alternative reduction of the same TESS

photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3582471353309229552, P=8.9404820160+/-0.0006222623d, e=0.422046, omega=315.8129deg. Closest edge-on conjunction offset-0.440570d (-0.049278phase), full-SB1-covariance linear propagated Gaia uncertainty0.230013d at the measured epoch. Near-Gaia-reference projected eclipse offset0.218213d (photometric period projection allowance0.107189d). The approximate central duration5.73h vs observed median3.25h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four real measured events in sectors99/102; adjacent cycles280/281 test recurrence. Historical sector38 adds independently extracted repeated events. Target deficit0.006pixel from target; nearest capable neighbor0.74pixel from deficit. Crowding and aperture dilution remain, but exact target-centered deficit/core favors target without a calibrated localization error.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

R303. TIC 220568520

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 220568520: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[1, 30, 97]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=18.5572206314 +/-0.0000259597d, reference eclipse epoch BTJD1337.7203277, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S2 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.121arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.083. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths19.851/19.780/19.532ppt, with 2 stacked events. QLP selected-kind fitted median19.549ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3472072559677245440, P=18.5622394903+/-0.0104861800d, e=0.056200, omega=167.8786deg. Closest edge-on conjunction offset-0.168961d (-0.009102phase), full-SB1-covariance linear propagated Gaia uncertainty0.673811d at the measured epoch. Near-Gaia-reference projected eclipse offset0.087001d (photometric period projection allowance0.001324d). The approximate central duration5.56h vs observed median4.93h permits noncentral geometry; this radius/minimum-mass estimate is not a

detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated flat-bottomed raw eclipses over sectors1/30/97. Near-gap asymmetric sector97 cycle141 has singular center covariance and is excluded from timing; sector1 cycle0 and clean sector97 cycle142 are retained. No capable neighbor under approximate flux-budget screen.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 276277940: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 9 distinct eclipse events in selected sectors[15, 76, 83]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=6.8645586129 +/-0.0000230538d, reference eclipse epoch BTJD1717.7413603, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S55 deficit peak[7, 8] vs target pixel[7, 7]; deficit-target separation4.635arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.931. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths109.693/109.506/90.147ppt, with 4 stacked events. QLP selected-kind fitted median150.628ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3216338427408009561 6, P=6.8634769946+/-0.0015596212d, e=0.171838, omega=314.6172deg. Closest edge-on conjunction offset0.141873d (0.020671phase), full-SB1-covariance linear propagated Gaia uncertainty0.270100d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.067961d (photometric period projection allowance0.004472d). The approximate central duration6.68h vs observed median4.75h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep raw eclipses recur across three sectors, with sector-dependent depths130-160ppt. Sector83 cycle271 singular center covariance is excluded from timing. Historical cutout1/3/5 depths109.7/109.5/90.1ppt show aperture dilution; no capable catalogued neighbor under approximate brightness screen.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

R305. TIC 406863699

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 406863699: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 3 distinct eclipse events in selected sectors[66, 101]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=16.7492445898 +/-0.0000238215d, reference eclipse epoch BTJD3105.4389091, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S65 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.749arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.153. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths32.830/32.671/33.367ppt, with 2 stacked events. QLP selected-kind fitted median34.841ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3577230606293467084 8, P=16.7429244065+/-0.0036265093d, e=0.221229, omega=96.3987deg. Closest edge-on conjunction offset0.881505d (0.052649phase), full-SB1-covariance linear propagated Gaia uncertainty0.520887d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.142364d (photometric period projection allowance0.003859d). The approximate central duration6.57h vs observed median3.05h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Three clear measured eclipses, including consecutive cycles88/89 in sector66 and recurrence in101; historical cutout65 also has two events. No capable neighbor under approximate flux-budget screen. Gaia conjunction offset0.053phase has propagated epoch uncertainty and approximate geometry, not an arbitrary significance veto.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R306. TIC 207148517

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 207148517: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[69, 97]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=7.7713883517 +/-0.0000320555d, reference eclipse epoch BTJD3187.7124533, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S97 deficit peak[8, 8] vs target pixel[7, 8]; deficit-target separation2.732arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual1.000. Capable neighbours: Gaia 4728689624881108864: 40.99 arcsec, G17.789, required fractional eclipse0.736
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths2.980/3.417/3.404ppt, with 8 stacked events. QLP selected-kind fitted median3.405ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3472868635582532352, P=7.7705559611+/-0.0010075925d, e=0.050853, omega=206.9657deg. Closest edge-on conjunction offset0.315934d (0.040658phase), full-SB1-covariance linear propagated Gaia uncertainty0.422468d at the measured epoch. Near-Gaia-reference projected eclipse offset0.016274d (photometric period projection allowance0.011540d). The approximate central duration5.68h vs observed median1.86h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Shallow repeat signal is measured in sectors69/97; individual fits vary and broad sector69 cycle236 is baseline-sensitive. Median depth is diluted. Historical PSF-scaled residual0.9997 is poor because bright off-center source dominates wide fit; local deficit core0.130pixel from target versus capable neighbor1.84pixels away supports target. Neighbor intrinsic requirement0.736 is not compared directly with its blended pixel fractional loss. Precision timing/shape is limited by low signal and baseline model.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R307. TIC 169657557

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 169657557: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 29 distinct eclipse events in selected sectors[61, 88]. The raw-event plot and numeric raw-windows.csv were inspected. The raw-windows.csv retains the initial broad linear model; deciding narrow-core fits and timings are in quadratic-core.json/png and measurements.json. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a quadratic baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 29 same-kind midtimes give P=1.4973843851 +/-0.0000030799d, reference eclipse epoch BTJD2965.1431096, kind: Narrow eclipse core atop broad phase modulation; physical primary identity unestablished. No center-covariance fits were excluded. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S88 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation2.086arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.505. Capable neighbours: Gaia 3036481615590722176: 29.04 arcsec, G12.512, required fractional eclipse0.037; Gaia 3036481615590722304: 30.71 arcsec, G16.598, required fractional eclipse0.957; Gaia 3036528443615800960: 49.79 arcsec, G14.030, required fractional eclipse0.104; Gaia 3036481512511513216: 55.32 arcsec, G15.668, required fractional eclipse0.415; Gaia 3036481615590721408: 55.33 arcsec, G16.556, required fractional eclipse0.920; Gaia 3036481478151775744: 56.40 arcsec, G13.060, required fractional eclipse0.051; Gaia 3036481443792033920: 57.17 arcsec, G14.265, required fractional eclipse0.125; Gaia 3036481409432298368: 57.87 arcsec, G16.577, required fractional eclipse0.938
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths17.702/13.538/9.801ppt, with 15 stacked events (quality-zero data). QLP selected-kind fitted median16.335ppt. This separately extracted cutout is an alternative reduction of

the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3303648151251150963 2, P=1.4974373957+/-0.0000740271d, e=0.111978, omega=21.7640deg. Closest edge-on conjunction offset-0.042512d (-0.028390phase), full-SB1-covariance linear propagated Gaia uncertainty0.137602d at the measured epoch. Near-Gaia-reference projected eclipse offset0.048667d (photometric period projection allowance0.005297d). The approximate central duration4.45h vs observed median2.41h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Broad phase modulation surrounds a sharper eclipse core. Quadratic-baseline narrow-core fit replaces the broad linear-baseline timing/depth model; core depth16.34ppt and duration2.41h are model-dependent. Earlier broad-model period agrees within formal errors. Target deficit0.099pixel, closest capable neighbor1.41pixels; all capable sources checked geometrically. No calibrated centroid uncertainty.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 363534683: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 10 distinct eclipse events in selected sectors[9, 36, 90]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a linear baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 10 same-kind midtimes give P=5.2864321424 +/-0.0000069133d, reference eclipse epoch BTJD1544.7583809, kind: Selected repeating eclipse; primary/secondary depth identity not established. No center-covariance fits were excluded. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S64 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.618arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.574. Capable neighbours: Gaia 5249644487609641344: 35.96 arcsec, G14.329, required fractional eclipse0.979
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths141.125/129.722/106.222ppt, with 5 stacked events (quality-zero data). QLP selected-kind fitted median144.520ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35249644448937154816, P=5.2864401901+/-0.0005018875d, e=0.048633, omega=239.4062deg. Closest edge-on conjunction offset-0.037278d (-0.007052phase), full-SB1-covariance linear propagated Gaia uncertainty0.097256d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.035516d (photometric period projection allowance0.001514d). The approximate central duration5.35h vs observed median4.27h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Ten raw eclipses across three sectors include adjacent repeats. Target deficit0.125pixel versus capable neighbor1.78pixels. Sector depths vary through aperture dilution; no claim of intrinsic constancy.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 21295315: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[20, 47, 60]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a linear baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=11.6068097551 +/-0.0000652497d, reference eclipse epoch BTJD1861.1294409, kind: Selected repeating eclipse; primary/secondary depth identity not established. No center-covariance fits were excluded. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S47 deficit peak[7, 7] vs target pixel[8, 7]; deficit-target separation0.471arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.288. Capable neighbours: Gaia 895666127653255552: 58.00 arcsec, G13.835, required fractional eclipse0.428
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths84.424/81.615/70.247ppt, with 3 stacked events (quality-zero data). QLP selected-kind fitted median87.584ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3895666402531207936, P=11.6050108508+/-0.0044449065d, e=0.299861, omega=90.5800deg. Closest edge-on conjunction offset0.251296d (0.021654phase), full-SB1-covariance linear propagated Gaia uncertainty0.732493d at the measured epoch. Near-Gaia-reference projected eclipse offset0.022835d (photometric period projection allowance0.008287d). The approximate central duration3.85h vs observed median3.24h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Five raw eclipses include consecutive cycles63/64/65 in sector47, testing recurrence. Target deficit0.022pixel versus capable neighbor2.73pixels. Gaia conjunction linear uncertainty0.73d limits phase inference.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 445438807: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 12 distinct eclipse events in selected sectors[18, 58, 85]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a linear baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 12 same-kind midtimes give P=3.6681590097 +/-0.0000037951d, reference eclipse epoch BTJD1795.6720263, kind: Selected repeating eclipse; primary/secondary depth identity not established. No center-covariance fits were excluded. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S58 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation3.948arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.712. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths84.862/73.669/64.838ppt, with 5 stacked events (quality-zero data). QLP selected-kind fitted median92.316ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3505891592075928320, P=3.6680210933+/-0.0002846168d, e=0.007003, omega=146.5116deg. Closest edge-on conjunction offset0.043915d (0.011973phase), full-SB1-covariance linear propagated Gaia uncertainty0.122864d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.008907d (photometric period projection allowance0.001454d). The approximate central duration3.83h vs observed median3.18h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Twelve quality-zero measured raw events over three sectors test recurrence. No capable neighbor within60arcsec under approximate Gaia flux budget; target deficit0.188pixel. Finite-cadence trapezoid and aperture dilution limit precision.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R311. TIC 394386248

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 394386248: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 2 distinct eclipse events in selected sectors[81]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a linear baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 2 same-kind midtimes give P=13.5773902434 +/-0.0016368077d, reference eclipse epoch BTJD3509.3712123, kind: Selected repeating eclipse; primary/secondary depth identity not established. No center-covariance fits were excluded. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S40 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.197arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.657. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths81.223/81.035/77.614ppt, with 2 stacked events (flag2048 cores). QLP selected-kind fitted median77.740ppt. Sector40 is a separate TESS observing occasion from the measured sector81 QLP events; its custom extraction is not an independent telescope. Alternative reductions of any one exposure share photons. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3204583764630507 5072, P=13.5745185100+/-0.0023485600d, e=0.333088, omega=30.2864deg. Closest edge-on conjunction offset0.613972d (0.045230phase), full-SB1-covariance linear propagated Gaia uncertainty0.499331d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.046526d (photometric period projection allowance0.376466d). The approximate central duration6.18h vs observed median4.46h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Two consecutive quality-zero sector81 eclipses measure only a13.58d timing baseline, with formal/cadence period error0.00164d; no long-baseline precision asserted. Custom TESScut sector40 contains two further13.5769d-spaced raw repeats, all cores flag2048; these are flagged supportive recurrence, not clean nulls or precise timing points. Flagged difference image target offset0.15pixel with no capable neighbor under approximate flux screen. Flagged-image systematic and 9x9 residual0.657 limit localization; raw sector81 eclipses are unflagged.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

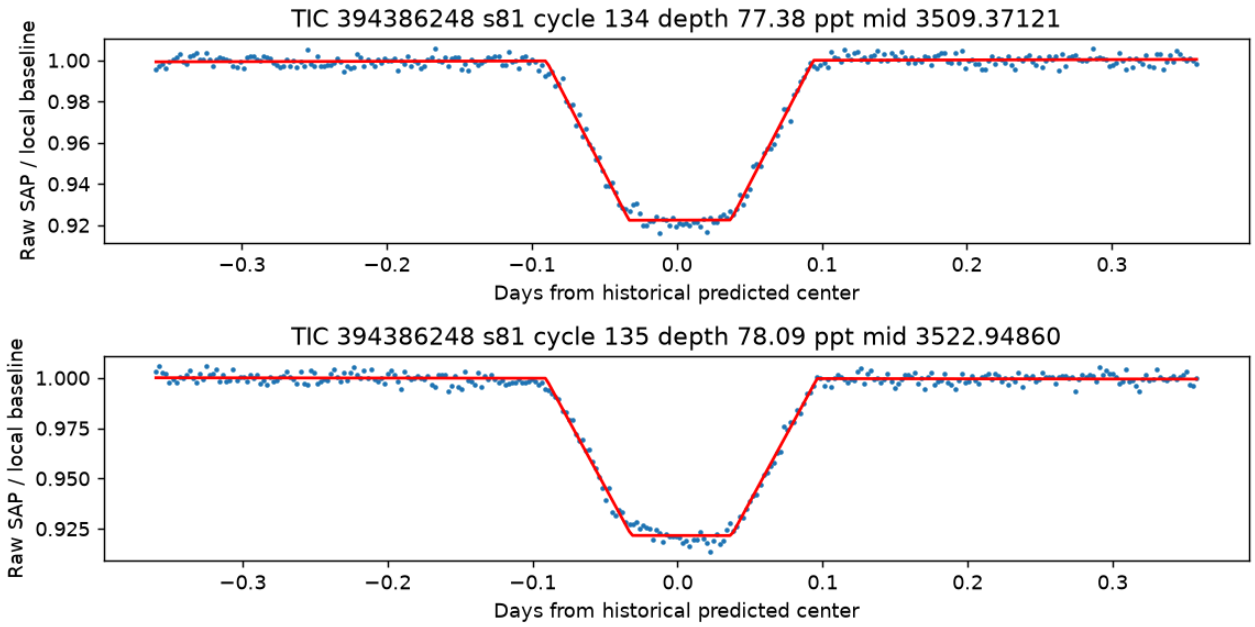
Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
81	134	3509.3712123	0.001157	77.385	selected
81	135	3522.9486025	0.001157	78.095	selected

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv; shared-qlp QLP FITS; historical/diff_s40_flag2048.json, historical/diff_s40_flag2048.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R311. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R311; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.

R312. TIC 403154475

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 403154475: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 15 distinct eclipse events in selected sectors[102, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a linear baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=5.0696716413 +/-0.0001354749d, reference eclipse epoch BTJD4132.0979108, kind: Even historical half-period eclipse parity; slightly deeper by sample median, physical primary unestablished. No center-covariance fits were excluded. Odd historical half-period cycles are omitted by event kind, not failed timing covariance. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S95 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.031arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.332. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths7.303/7.076/7.059ppt, with 10 stacked events (quality-zero data). QLP selected-kind fitted median7.954ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3650830636904073292 8, P=5.0699604109+/-0.0003054710d, e=0.011145, omega=306.9271deg. Closest edge-on conjunction offset0.021105d (0.004163phase), full-SB1-covariance linear propagated Gaia uncertainty0.221143d at the measured epoch. Near-Gaia-reference projected eclipse offset0.234217d (photometric period projection allowance0.099981d). The approximate central duration6.00h vs observed median1.96h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Raw dips recur near2.535d, but Gaia orbit is5.06996d. Fit uses even half-period cycles1106,1108,1110,1112,1126,1128 as same-kind events; even median7.954ppt versus odd7.308ppt is not decisive physical-primary identification. Odd-only independent period5.0695421d agrees. Orbital5.0696716d interpretation uses same-kind parity and Gaia geometry; half-period dip recurrence is not silently called orbital period. No capable neighbor under flux-budget screen.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 137837801: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[28, 68, 96]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a linear baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=7.1214903232 +/-0.0000068804d, reference eclipse epoch BTJD2062.5703486, kind: Selected repeating eclipse; primary/secondary depth identity not established. No center-covariance fits were excluded. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S28 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation3.658arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.035. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths292.097/293.233/291.190ppt, with 3 stacked events (quality-zero data). QLP selected-kind fitted median310.685ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3682166147923933248O, P=7.1214539995+/-0.0004287017d, e=0.024797, omega=143.1801deg. Closest edge-on conjunction offset-0.031138d (-0.004372phase), full-SB1-covariance linear propagated Gaia uncertainty0.107759d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.039674d (photometric period projection allowance0.001617d). The approximate central duration4.86h vs observed median3.67h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Eight deep raw eclipses over sectors28/68/96 include adjacent cycles0/1/2; aperture and sector depth differences reflect dilution/modeling. No capable neighbor under approximate Gaia flux budget.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

R314. TIC 442606056

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 442606056: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[12, 65, 103]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a linear baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=5.3867042118 +/-0.0000046689d, reference eclipse epoch BTJD1651.0703266, kind: Selected repeating eclipse; primary/secondary depth identity not established. No center-covariance fits were excluded. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S65 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.973arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.905. Capable neighbours: Gaia 6015192755661126144: 8.81 arcsec, G12.576, required fractional eclipse0.165; Gaia 6015192790020864256: 50.94 arcsec, G13.336, required fractional eclipse0.259; Gaia 6015192790020865024: 56.30 arcsec, G14.423, required fractional eclipse0.581
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths51.676/42.364/34.810ppt, with 4 stacked events (quality-zero data). QLP selected-kind fitted median75.874ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR36015192755661126400, P=5.3867234906+/-0.0003950484d, e=0.026677, omega=105.4305deg. Closest edge-on conjunction offset-0.034817d (-0.006463phase), full-SB1-covariance linear propagated Gaia uncertainty0.107917d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.030306d (photometric period projection allowance0.001093d). The approximate central

duration5.75h vs observed median3.81h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Crowded unresolved field: deficit0.189pixel from target versus closest capable G12.6neighbor0.62pixel. Deficit maximum is target pixel and centroid is displaced away from this neighbor, favoring target. No calibrated localization uncertainty, so resolved photometry remains useful. Intrinsic neighbor requirement is not compared directly to blended pixel loss.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 50993470: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[33, 87]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a linear baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=9.1725585235 +/-0.0000429318d, reference eclipse epoch BTJD2209.6611630, kind: Selected repeating eclipse; primary/secondary depth identity not established. No center-covariance fits were excluded. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S87 deficit peak[7, 7] vs target pixel[7, 8]; deficit-target separation6.770arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.368. Capable neighbours: Gaia 3060034048014175872: 20.39 arcsec, G15.883, required fractional eclipse0.766; Gaia 3060033670057058304: 24.05 arcsec, G15.444, required fractional eclipse0.519; Gaia 3060033738776540032: 32.91 arcsec, G13.452, required fractional eclipse0.101; Gaia 3060033738776539648: 56.79 arcsec, G15.713, required fractional eclipse0.658; Gaia 3060033841855741696: 59.65 arcsec, G15.790, required fractional eclipse0.705
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths21.254/20.020/17.898ppt, with 3 stacked events (quality-zero data). QLP selected-kind fitted median25.260ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3306003367005705715 2, P=9.1714284019+/-0.0021381464d, e=0.183579, omega=151.0942deg. Closest edge-on conjunction offset0.179966d (0.019622phase), full-SB1-covariance linear propagated Gaia uncertainty0.476695d

at the measured epoch. Near-Gaia-reference projected eclipse offset-0.043798d (photometric period projection allowance0.008500d). The approximate central duration5.06h vs observed median2.31h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Five measured raw eclipses in sectors33/87 include consecutive cycles78/79 and237/238/239, testing recurrence. Sector7 lacks qualifying fitted events and is not claimed a clean null. Target deficit0.322pixel versus nearest capable neighbor1.32pixels; centroid uncertainty uncalibrated. Baseline slope and dilution affect depth.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R316. TIC 367362188

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 367362188: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free eclipse-core fits to quality-zero raw QLP SAP_FLUX show 14 distinct eclipse events in selected sectors[19, 59, 86]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local baseline, free depth, center, duration and ingress were fitted with a linear baseline; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 14 same-kind midtimes give P=3.8453405155 +/-0.0000036346d, reference eclipse epoch BTJD1818.1697582, kind: Selected repeating eclipse; primary/secondary depth identity not established. No center-covariance fits were excluded. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Saved S44 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation4.492arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.754. Capable neighbours: Gaia 185367425540565760: 30.23 arcsec, G14.918, required fractional eclipse0.744
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths53.953/50.016/40.001ppt, with 6 stacked events (quality-zero data). QLP selected-kind fitted median54.935ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3185367421242800768, P=3.8451064321+/-0.0003851350d, e=0.091429, omega=237.6746deg. Closest edge-on conjunction offset-0.022555d (-0.005866phase), full-SB1-covariance linear propagated Gaia uncertainty0.145341d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.109634d (photometric period projection allowance0.001352d). The approximate central duration5.04h vs observed median3.89h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Fourteen raw eclipses across three sectors include consecutive cycles285/286 and multiple later repeats. Target deficit0.214pixel versus capable neighbor1.71pixels; depth and timing remain finite-cadence/model-dependent.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R317. TIC 388152396

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization.

Archived source: sanitized report text.

TIC 388152396: CONFIRMED

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 4 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[54, 81] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: pass at the retained photometric cycle assignment.** P=10.9089333454 +/-0.0000386161d, epoch BTJD2780.52659071; epoch kind: Selected shallower eclipse. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Selected shallower eclipse at phase0; deeper distinct eclipse near phase0.34. S81 cycle67 unrelated local dip +0.20..0.45d masked from baseline fit; both sides retained. No half/double adoption. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS resolution with limitations below.** Identity: Gaia DR31807113502749250176; cutout WCS and selected target agree. Lost-light centroid is0.052px from target; peak[8, 7] versus target pixel[8, 7]. Historical PSF residual0.476. Capable-neighbour review: Gaia1807113953736371840 at37.90arcsec, required intrinsic fractional eclipse0.958, distance from deficit1.823px Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S54 gives1x1/3x3/5x5 aperture depths103.520/97.563/84.866ppt from1 stacked event(s). QLP fitted selected-event median is108.190ppt. These are reductions of the same TESS photons, not independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.
5. **Gaia orbital geometry: consistent within the stated bounded approximations.** Full NSS orbit: P=10.9092234063+/-0.0025822378d, e=0.483069, omega=297.6635deg, periastron

BTJD391.840072. Measured-Gaia period difference-0.00029006d. Closest edge-on conjunction offset-0.170945d (-0.015670phase); full covariance linear propagated error0.591585d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.159138solar masses; assumed primary mass1.189, minimum companion mass0.880. Approximate central duration5.49h versus fitted median5.14h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Reference epoch is the selected shallower eclipse; a deeper eclipse near phase0.34 supports an eccentric binary at the retained period. S54 selected-event depth varies about110–134ppt; no common intrinsic depth is inferred. An unrelated local dip at +0.20..0.45d in S81 cycle67 was removed from baseline fitting, with baseline on both sides retained. The period changes by only0.00000312d relative to the unmasked fit; this is a model-sensitivity comparison, not a total uncertainty.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization.

Archived source: sanitized report text.

TIC 63577915: CONFIRMED

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 6 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[7, 34, 87] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: pass at the retained photometric cycle assignment.** P=14.4103324466 +/-0.0000232127d, epoch BTJD1497.60282988; epoch kind: Selected phase-zero eclipse; not assumed deepest primary. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Representative raw events support same event kind at retained photometric period; no persistent unequal alternating sequence seen. The measured period is seeded by the historical photometric branch, not an exhaustive alias search. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS resolution with limitations below.** Identity: Gaia DR3292128093763109644 8; cutout WCS and selected target agree. Lost-light centroid is0.145px from target; peak[8, 8] versus target pixel[8, 8]. Historical PSF residual0.902. Capable-neighbour review: No listed neighbour within60arcsec passes the approximate G-band flux-budget screen. Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S7 gives1x1/3x3/5x5 aperture depths224.852/220.968/205.231ppt from2 stacked event(s). QLP fitted selected-event median is226.649ppt. These are reductions of the same TESS photons, not independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.

5. **Gaia orbital geometry: consistent within the stated bounded approximations.** Full NSS orbit: P=14.4142632131+/-0.0018573652d, e=0.554808, omega=287.4635deg, periastron BTJD388.188059. Measured-Gaia period difference-0.00393077d. Closest edge-on conjunction offset-0.315064d (-0.021858phase); full covariance linear propagated error0.128221d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.204064solar masses; assumed primary mass1.260, minimum companion mass1.020. Approximate central duration8.75h versus fitted median7.08h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Large scaled-out-image PSF residual0.902 is not alone a failed attribution check: deficit core is on target, and no listed Gaia neighbour within60arcsec can supply the eclipse under the approximate G-band flux budget. No calibrated centroid ellipse is available.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

R319. TIC 11249710

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization.

Archived source: sanitized report text.

TIC 11249710: CONFIRMED

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 7 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[41, 74, 81] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: pass at the retained photometric cycle assignment.** P=8.3357588781 +/-0.0000195304d, epoch BTJD2423.91922976; epoch kind: Selected phase-zero eclipse; not assumed deepest primary. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Two distinct similar-depth eclipses at phases0 and0.34 establish retained eccentric orbital period; selected phase0 event kind, not claim deepest primary. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS resolution with limitations below.** Identity: Gaia DR32028395616657465856; cutout WCS and selected target agree. Lost-light centroid is0.306px from target; peak[7, 7] versus target pixel[7, 7]. Historical PSF residual0.595. Capable-neighbour review: Gaia2028394139188718336 at19.48arcsec, required intrinsic fractional eclipse0.827, distance from deficit1.283px; Gaia2028394139188714624 at26.32arcsec, required intrinsic fractional eclipse0.632, distance from deficit1.460px; Gaia2028394070469231616 at36.26arcsec, required intrinsic fractional eclipse0.458, distance from deficit1.777px; Gaia2028394070469227648 at56.99arcsec, required intrinsic fractional eclipse0.615, distance from deficit2.805px Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S55 gives1x1/3x3/5x5 aperture depths79.059/62.084/47.787ppt from3 stacked event(s). QLP fitted selected-event median is97.705ppt. These are reductions of the same TESS photons, not

independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.

5. **Gaia orbital geometry: consistent within the stated bounded approximations.** Full NSS orbit: P=8.3358909655+/-0.0014033620d, e=0.270374, omega=10.1155deg, periastron BTJD391.571708. Measured-Gaia period difference-0.00013209d. Closest edge-on conjunction offset-0.015004d (-0.001800phase); full covariance linear propagated error0.345895d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.221877solar masses; assumed primary mass1.000, minimum companion mass0.942. Approximate central duration7.99h versus fitted median8.60h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Crowded field with four capable neighbours. The deficit is0.306pixel from target and1.283pixels from the closest capable neighbour, so the target is favored at TESS resolution; precise exclusion probabilities are unavailable. Alternative S55 target-centered aperture gives about62ppt in three events, versus QLP about100ppt; dilution and aperture differences prevent an intrinsic-depth equality claim. Second eclipse near phase0.34 supports retained orbital period.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

TIC 150582131: CONFIRMED

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 4 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[25, 52, 79] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: pass at the retained photometric cycle assignment.** P=17.2887175714 +/-0.0000991015d, epoch BTJD2003.32337520; epoch kind: Selected phase-zero eclipse; not assumed deepest primary. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Representative raw events support same event kind at retained photometric period; no persistent unequal alternating sequence seen. The measured period is seeded by the historical photometric branch, not an exhaustive alias search. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS resolution with limitations below.** Identity: Gaia DR3456167294533319769 6; cutout WCS and selected target agree. Lost-light centroid is0.053px from target; peak[7, 8] versus target pixel[7, 7]. Historical PSF residual0.220. Capable-neighbour review: No listed neighbour within60arcsec passes the approximate G-band flux-budget screen. Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S79 gives1x1/3x3/5x5 aperture depths75.715/77.209/76.104ppt from1 stacked event(s). QLP fitted selected-event median is79.070ppt. These are reductions of the same TESS photons, not independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.

5. **Gaia orbital geometry: consistent within the stated bounded approximations.** Full NSS orbit: P=17.2926454274+/-0.0113118760d, e=0.110523, omega=31.1277deg, periastron BTJD392.576071. Measured-Gaia period difference-0.00392786d. Closest edge-on conjunction offset0.201874d (0.011674phase); full covariance linear propagated error1.022039d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.0175455solar masses; assumed primary mass1.000, minimum companion mass0.311. Approximate central duration5.62h versus fitted median7.11h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Repeated deep events include consecutive S79 cycles84/85. Approximate central-duration estimate is shorter than the fitted width; TIC radii and assumed main-sequence minimum-mass companion are uncertain, so this is not a fitted binary-radius solution or a quantitative duration match.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization.

Archived source: sanitized report text.

TIC 47653432: CONFIRMED

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 10 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[65, 102] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: pass at the retained photometric cycle assignment.** P=4.1981909010 +/-0.0000097735d, epoch BTJD3071.05142551; epoch kind: Selected phase-zero eclipse; not assumed deepest primary. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Representative raw events support same event kind at retained photometric period; no persistent unequal alternating sequence seen. The measured period is seeded by the historical photometric branch, not an exhaustive alias search. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS resolution with limitations below.** Identity: Gaia DR3621566090395219353 6; cutout WCS and selected target agree. Lost-light centroid is0.148px from target; peak[7, 7] versus target pixel[7, 7]. Historical PSF residual0.358. Capable-neighbour review: Gaia6215657949014886144 at43.41arcsec, required intrinsic fractional eclipse0.060, distance from deficit2.162px; Gaia6215657949014692480 at44.25arcsec, required intrinsic fractional eclipse0.395, distance from deficit2.101px; Gaia6215666779467456384 at48.79arcsec, required intrinsic fractional eclipse0.599, distance from deficit2.434px; Gaia6215663824529954048 at52.66arcsec, required intrinsic fractional eclipse0.368, distance from deficit2.626px Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S38 gives1x1/3x3/5x5 aperture depths4.853/4.373/4.511ppt from6 stacked event(s). QLP

fitted selected-event median is5.090ppt. These are reductions of the same TESS photons, not independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.

5. **Gaia orbital geometry: consistent within the stated bounded approximations.** Full NSS orbit: P=4.1924134926+/-0.0013497127d, e=0.059512, omega=347.9732deg, periastron BTJD390.987237. Measured-Gaia period difference0.00577741d. Closest edge-on conjunction offset0.002164d (0.000516phase); full covariance linear propagated error0.827753d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.0131992solar masses; assumed primary mass1.120, minimum companion mass0.298. Approximate central duration5.17h versus fitted median1.54h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Shallow4–7ppt locally normalized events recur with resolved localized shape; the whole-sector raw fold is dominated by baseline trends. Four capable neighbours are43arcsec or farther away from the compact target deficit. Observed duration about1.54h versus approximate central5.17h can arise from projected chord/radius assumptions; no measured central-duration match is claimed.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

TIC 94113033: CONFIRMED

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 6 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[54, 81] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: pass at the retained photometric cycle assignment.** P=4.9193469541 +/-0.0000326822d, epoch BTJD2773.32107341; epoch kind: Selected phase-zero eclipse; not assumed deepest primary. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Representative raw events support same event kind at retained photometric period; no persistent unequal alternating sequence seen. The measured period is seeded by the historical photometric branch, not an exhaustive alias search. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS resolution with limitations below.** Identity: Gaia DR34289984996506672128; cutout WCS and selected target agree. Lost-light centroid is0.129px from target; peak[8, 7] versus target pixel[8, 7]. Historical PSF residual0.947. Capable-neighbour review: No listed neighbour within60arcsec passes the approximate G-band flux-budget screen. Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S81 gives1x1/3x3/5x5 aperture depths61.891/60.642/55.953ppt from3 stacked event(s). QLP fitted selected-event median is65.306ppt. These are reductions of the same TESS photons, not independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.

5. **Gaia orbital geometry: consistent within the stated bounded approximations.** Full NSS orbit: P=4.9192335218+/-0.0003838993d, e=0.256995, omega=223.8411deg, periastron BTJD389.127892. Measured-Gaia period difference0.00011343d. Closest edge-on conjunction offset-0.138537d (-0.028162phase); full covariance linear propagated error0.239835d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.0286867solar masses; assumed primary mass1.150, minimum companion mass0.412. Approximate central duration6.89h versus fitted median5.29h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Large scaled-out-image PSF residual0.947 is not alone a failed attribution check: deficit core is on target and no listed neighbour passes the approximate flux-budget screen. No calibrated centroid uncertainty is available.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

TIC 314991763: CONFIRMED

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 6 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[56, 83] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: pass at the retained photometric cycle assignment.** P=7.7113830155 +/-0.0000099460d, epoch BTJD2833.13055669; epoch kind: Selected phase-zero eclipse; not assumed deepest primary. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Deep primary phase0 and shallower secondary phase0.5 establish full orbital period. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS resolution with limitations below.** Identity: Gaia DR31777474556207679872; cutout WCS and selected target agree. Lost-light centroid is0.106px from target; peak[7, 7] versus target pixel[7, 7]. Historical PSF residual0.301. Capable-neighbour review: Gaia1777474590567419776 at56.26arcsec, required intrinsic fractional eclipse0.649, distance from deficit2.718px Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S56 gives1x1/3x3/5x5 aperture depths124.344/116.460/102.295ppt from4 stacked event(s). QLP fitted selected-event median is148.371ppt. These are reductions of the same TESS photons, not independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.
5. **Gaia orbital geometry: consistent within the stated bounded approximations.** Full NSS orbit: P=7.7109095009+/-0.0008394808d, e=0.012496, omega=74.8256deg, periastron BTJD388.328610. Measured-Gaia period difference0.00047351d. Closest edge-on conjunction

offset0.126569d (0.016414phase); full covariance linear propagated error0.268207d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.101794solar masses; assumed primary mass0.965, minimum companion mass0.640. Approximate central duration6.40h versus fitted median4.56h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Unequal phase-zero primary and phase-half secondary establish the retained full orbital period. One capable neighbour at56.26arcsec is separated from the compact target deficit.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Sector	Historical photometric cycle	Measured midpoint BTJD	Fit-input error d	Depth ppt

next_check: Resolved eclipse photometry or multi-source PRF localization.

Archived source: sanitized report text.

TIC 102716983: PROBABLE

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 4 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[19, 59, 73] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: pass at the retained photometric cycle assignment.** P=11.6869371250 +/-0.0000409829d, epoch BTJD1818.04578377; epoch kind: Selected phase-zero eclipse; not assumed deepest primary. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Extra S59 QLP downloaded because initial three selected sectors yielded only two timed events. S59 cycles94,95 now provide consecutive recurrence and four timed eclipses total. Close capable neighbours14.39/14.45arcsec remain attribution concern. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after checking capable neighbours.** Identity: Gaia DR3490460942806688768; cutout WCS and selected target agree. Lost-light centroid is0.134px from target; peak[8, 7] versus target pixel[8, 7]. Historical PSF residual0.920. Capable-neighbour review: Gaia490460942808112640 at14.39arcsec, required intrinsic fractional eclipse0.323, distance from deficit0.665px; Gaia490460942803537408 at14.45arcsec, required intrinsic fractional eclipse0.263, distance from deficit0.660px; Gaia490460942808113408 at26.56arcsec, required intrinsic fractional eclipse0.702, distance from deficit1.389px Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S59 gives1x1/3x3/5x5 aperture depths32.791/35.271/21.366ppt from1 stacked event(s). QLP fitted selected-event median is61.617ppt. These are reductions of the same TESS photons, not

independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.

5. **Gaia orbital geometry: consistent within the stated bounded approximations.** Full NSS orbit: P=11.6869282788+/-0.0014018231d, e=0.104485, omega=170.1550deg, periastron BTJD394.383940. Measured-Gaia period difference0.00000885d. Closest edge-on conjunction offset0.081490d (0.006973phase); full covariance linear propagated error0.150298d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.0465559solar masses; assumed primary mass1.000, minimum companion mass0.464. Approximate central duration10.99h versus fitted median6.52h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Repeating eclipses are secure, including consecutive S59 cycles94/95 measured after supplementing the original selection. Attribution is unresolved: two capable neighbours at14.39/14.45arcsec lie within one TESS pixel, and the historical PSF residual is0.920. The third capable neighbour is26.56arcsec away. Source localization requires resolved imaging or multi-source PRF analysis.

Next check: Resolved eclipse photometry or multi-source PRF localization.

Sector	Historical photometric cycle	Measured midpoint BTJD	Fit-input error d	Depth ppt

TIC 115048464: CONFIRMED

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 7 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[19, 45, 86] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: pass at the retained photometric cycle assignment.** P=8.0142430574 +/-0.0000142842d, epoch BTJD1832.46809862; epoch kind: Selected phase-zero eclipse; not assumed deepest primary. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Representative raw events support same event kind at retained photometric period; no persistent unequal alternating sequence seen. The measured period is seeded by the historical photometric branch, not an exhaustive alias search. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS resolution with limitations below.** Identity: Gaia DR3183073672486786048; cutout WCS and selected target agree. Lost-light centroid is0.201px from target; peak[7, 8] versus target pixel[7, 8]. Historical PSF residual0.791. Capable-neighbour review: Gaia183073775565996672 at51.03arcsec, required intrinsic fractional eclipse0.682, distance from deficit2.572px Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S19 gives1x1/3x3/5x5 aperture depths37.833/39.394/37.099ppt from4 stacked event(s). QLP fitted selected-event median is37.720ppt. These are reductions of the same TESS photons, not independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.

5. **Gaia orbital geometry: consistent within the stated bounded approximations.** Full NSS orbit: P=8.0157041322+/-0.0019466464d, e=0.050791, omega=286.7691deg, periastron BTJD386.221698. Measured-Gaia period difference-0.00146107d. Closest edge-on conjunction offset-0.176019d (-0.021959phase); full covariance linear propagated error0.411170d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.0445999solar masses; assumed primary mass1.150, minimum companion mass0.494. Approximate central duration8.19h versus fitted median4.70h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Fitted duration and depth change across cadence/sector apertures; no precision intrinsic depth or common duration is claimed. The capable neighbour at51.03arcsec is separated from the target-core deficit.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

physical_verdict: PLAUSIBLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolve cycle-count aliases with an observed adjacent eclipse and resolve source localization.

Archived source: sanitized report text.

TIC 331861613: PLAUSIBLE

Full bounded review: COMPLETE. All five checks were performed; scientific uncertainty is retained separately from execution completeness. Catalogue novelty is supplied by the shared scoped catalogue receipts and is not inferred from this physical classification.

1. **Raw repeated events: pass.** 3 usable free-center trapezoid fits to quality-zero raw QLP SAP_FLUX in sectors[17, 18, 85] show localized eclipse morphology. Numeric raw-windows.csv and raw-events.png are deciding artifacts. Initial selection uses up to three widely separated available sectors; the two apparent two-event cases received bounded extra earlier-sector checks. Flagged and uncovered windows are never called clean negatives. A local linear baseline, depth, center, duration and ingress are fitted; no Gaia-fixed center is used as a measured midpoint.
2. **Eclipse timing: conditional; cycle aliases unresolved.** P=18.1534618869 +/-0.0000784945d, epoch BTJD1770.97977338; epoch kind: Selected phase-zero eclipse; not assumed deepest primary. The legacy CSV name primary_epoch_btjd does not assert this is the deeper eclipse. Cycle assignments start from the historical photometric branch; an independently recomputed weighted linear fit reproduces all numbers. Extra earlier S18 downloaded because initial three sectors yielded only two timed events. S17 cycle0,S18 cycle2,S85 cycle102 repeat at three epochs, but no adjacent-cycle pair; S58 cycle62 has zero quality-zero samples in +/-0.2d, not null. Integer/subharmonic ambiguity requires helper decision; full available QLP list17,18,58,85 checked. Close capable14arcsec neighbour also unresolved. This is a bounded recurrence/morphology audit, not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after checking capable neighbours.** Identity: Gaia DR3410380178061244416; cutout WCS and selected target agree. Lost-light centroid is0.049px from target; peak[8, 7] versus target pixel[8, 7]. Historical PSF residual0.538. Capable-neighbour review: Gaia410380178061244800 at13.99arcsec, required intrinsic fractional eclipse0.726, distance from deficit0.684px; Gaia410380173765981056 at23.03arcsec, required intrinsic fractional eclipse0.441, distance from deficit1.173px; Gaia410380139406239744 at40.59arcsec, required intrinsic fractional eclipse0.432, distance from deficit2.010px; Gaia410380105046671488 at45.04arcsec, required intrinsic fractional eclipse0.509, distance from deficit2.255px; Gaia410380109341769472 at45.33arcsec, required intrinsic fractional eclipse0.105, distance from deficit2.276px; Gaia410380276842680320 at45.50arcsec, required intrinsic fractional eclipse0.582, distance from deficit2.332px; Gaia410380349860139520 at46.18arcsec, required intrinsic fractional eclipse0.869,

distance from deficit2.297px; Gaia410380349859937920 at48.73arcsec, required intrinsic fractional eclipse0.528, distance from deficit2.435px; Gaia410380143701508736 at50.61arcsec, required intrinsic fractional eclipse0.617, distance from deficit2.518px; Gaia410380384219876096 at52.48arcsec, required intrinsic fractional eclipse0.170, distance from deficit2.586px; Gaia410380315500194944 at54.27arcsec, required intrinsic fractional eclipse0.035, distance from deficit2.746px; Gaia410380178061247488 at57.67arcsec, required intrinsic fractional eclipse0.840, distance from deficit2.834px Required intrinsic eclipse fractions and observed blended-pixel fractional losses have different dilution and are not compared as a veto. No calibrated centroid confidence ellipse or precise exclusion probability is claimed.

4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut S17 gives1x1/3x3/5x5 aperture depths10.223/9.849/7.372ppt from1 stacked event(s). QLP fitted selected-event median is11.888ppt. These are reductions of the same TESS photons, not independent observations. Different apertures, dilution and possible mixed eclipse-kind stacks preclude a claim of equal intrinsic depth.
5. **Gaia orbital geometry: conditional on the unresolved photometric cycle assignment.** Full NSS orbit: P=18.1514556913+/-0.0021802734d, e=0.451459, omega=336.4939deg, periastron BTJD388.294085. Measured-Gaia period difference0.00200620d. Closest edge-on conjunction offset0.124221d (0.006844phase); full covariance linear propagated error0.232960d at the measured epoch. Both conjunction branches and covariance details are retained in gaia-geometry.json. Mass function0.0485949solar masses; assumed primary mass1.050, minimum companion mass0.486. Approximate central duration13.51h versus fitted median5.61h uses TIC radius and an assumed main-sequence minimum-mass companion, not a fitted geometry. There is no arbitrary sigma veto, and neither this duration estimate nor the formal timing error establishes precision orbital association.

Limitations: Three measured events at historical cycles0,2,102 repeat, but no adjacent-cycle pair fixes the integer/subharmonic choice. The18.15346d ephemeris and its conditional fit error assume those cycle assignments; alternative periods remain unresolved. Available archived sectors17,18,58,85 were checked, including added earlierS18. S58 cycle62 has zero quality-zero samples within0.2d, so it is not a null. Twelve capable neighbours include one at13.99arcsec; attribution also remains unresolved.

Next check: Resolve cycle-count aliases with an observed adjacent eclipse and resolve source localization.

Sector	Historical photometric cycle	Measured midpoint BTJD	Fit-input error d	Depth ppt
17	0	1770.97990271	0.01041681	11.068
18	2	1807.28656523	0.01041651	11.888
85	102	3622.63288604	0.00293361	11.959

R327. TIC 240786248

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 240786248

CONFIRMED; full_review_completion COMPLETE. The bounded five checks are complete; physical uncertainty is retained separately. Gaia DR3 G=12.003646; inventory G=12.0119.

Raw events and timing: 7 accepted measured centers in sectors [57, 58, 84, 85], cycles [100, 102, 168, 170, 103, 105, 171]. Selected period/separation 10.7677990999 +/- 1.31461e-05 days; epoch BTJD 2854.3337057380 (Selected phase-zero eclipse; deepest primary not assumed). Median QLP raw depth 75.4ppt. Predicted centers only guide windows; timings are fitted centers. Singular or zero-covariance fits are excluded. Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.

Attribution: historical sector57 difference deficit lies 0.065px from target. WCS target identity agrees with Gaia 4151783093676200 96; coordinate check 2.68e-11arcsec. No capable Gaia neighbor within the historical60arcsec list. Intrinsic neighbor eclipse requirements and blended pixel losses have different dilution and are not compared as a veto. Historical image and capable-neighbor numeric audit support target attribution.

Alternative reduction: historical custom TESScut3x3 event depths [78.019, 77.5]ppt. These repeat the eclipse pattern in a separate extraction of the same TESS photons; they are not independent observing occasions.

Gaia geometry: full NSS correlation vector propagated at observed epoch. Gaia P=10.76826206 +/- 0.0013796d, eccentricity 0.32715; nearest edge-on conjunction offset -0.062046d (-0.0057619phase), descriptive linear covariance error 0.32855d. Mass function 0.018245solar, approximate central duration 5.697h versus representative measured 4.762h. Duration uses TIC radius and main-sequence minimum-mass companion and is not a fitted physical solution. This supports physical plausibility without an arbitrary sigma veto.

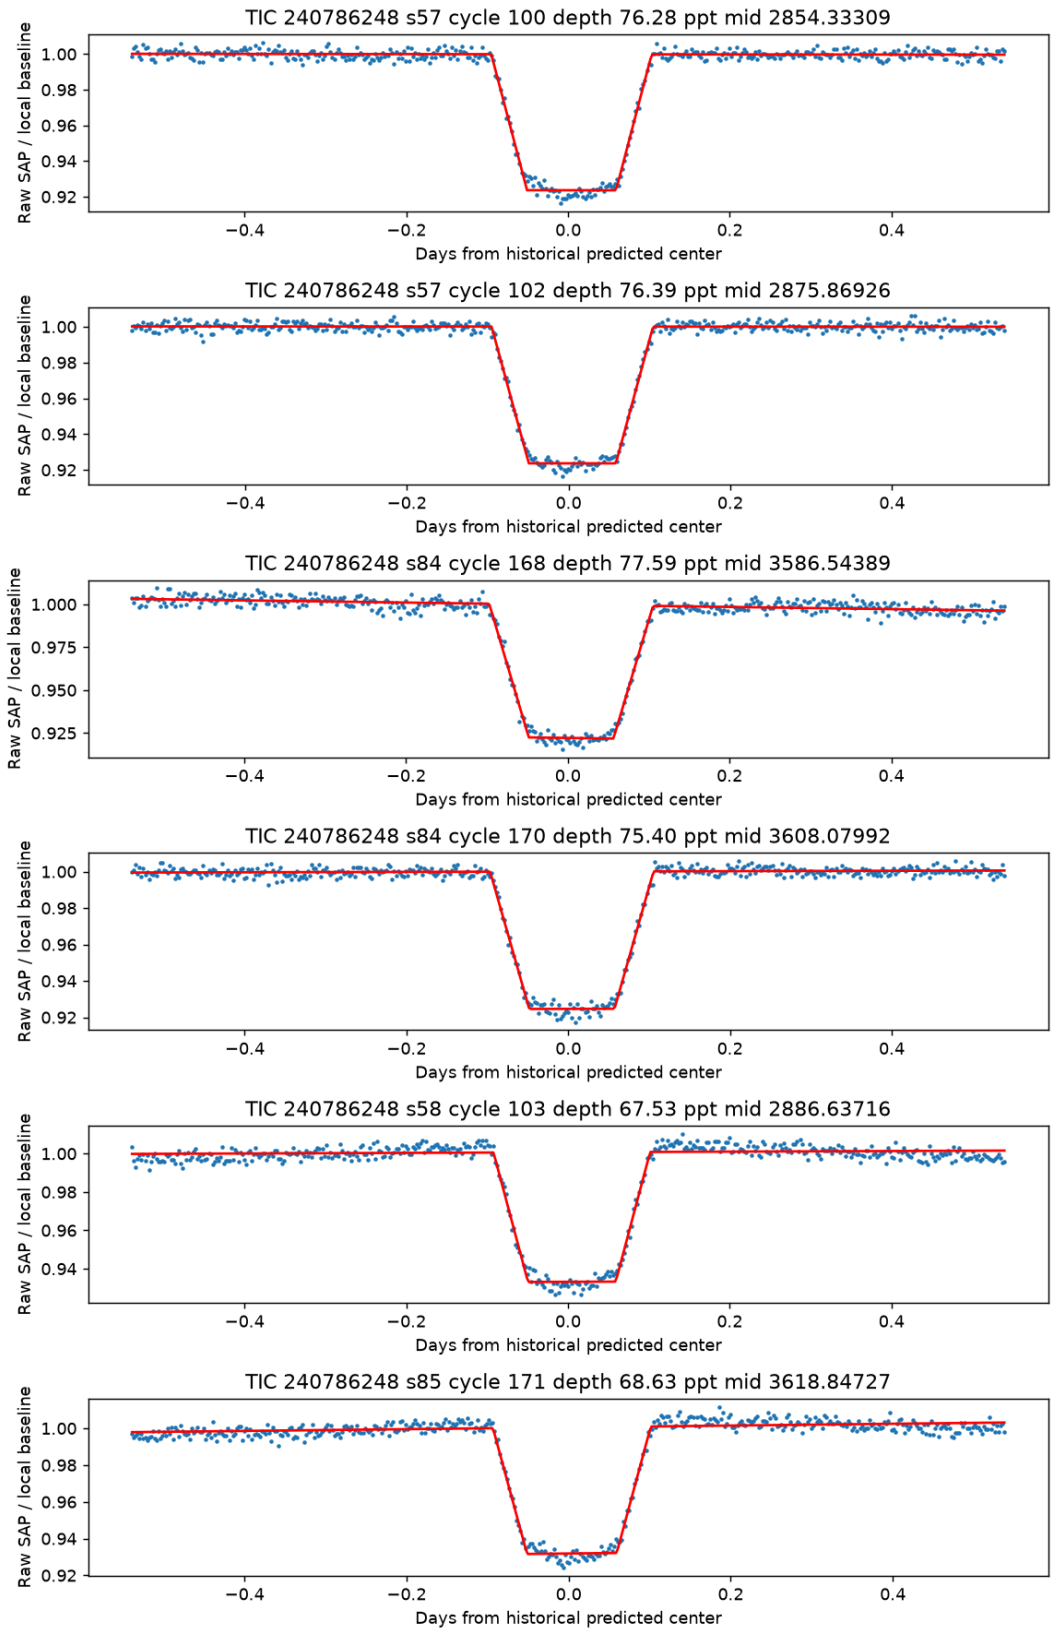
Limitations: Seven measured eclipses include consecutive cross-sector cycles102/103 and170/171 after checking all five available QLP sectors17,57,58,84,85. Even/odd depths are confounded with sectors/apertures; they do not independently exclude an orbital double alias. Repeated morphology, actual spacing and Gaia period support the retained association. Depths depend on aperture dilution and local baseline. Pixel centroid uncertainties and timing systematics are not calibrated.

Next check: Optional precision characterization.

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-windows.csv, raw-events.png, historical/diff_s57.json; batch alias-audit.json, recurrence-coverage.json, pixel-audit.json, gaia-geometry.json, download-receipts.json and

SHA256SUMS.json. Catalogue novelty is supplied separately by shared-catalogues and does not determine this physical verdict. No claim of exhaustive literature priority.

Stable review key: R327. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R327; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.

Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.

Attribution: historical sector30 difference deficit lies 0.166px from target. WCS target identity agrees with Gaia 4948003127599399936; coordinate check 0arcsec. Gaia 4948003127599400064: separation 26.21arcsec, deficit distance 1.287px, required intrinsic fraction 0.242 Intrinsic neighbor eclipse requirements and blended pixel losses have different dilution and are not compared as a veto. Helper inspected target/neighbor image morphology.

Alternative reduction: historical custom TESScut3x3 event depths [16.668, 15.479]ppt. These repeat the eclipse pattern in a separate extraction of the same TESS photons; they are not independent observing occasions.

Gaia geometry: full NSS correlation vector propagated at observed epoch. Gaia P=17.15732289 +/- 0.0052721d, eccentricity 0.39269; nearest edge-on conjunction offset 0.27282d (0.015901phase), descriptive linear covariance error 0.42285d. Mass function 0.13212solar, approximate central duration 5.512h versus representative measured 2.204h. Duration uses TIC radius and main-sequence minimum-mass companion and is not a fitted physical solution. This supports physical plausibility without an arbitrary sigma veto.

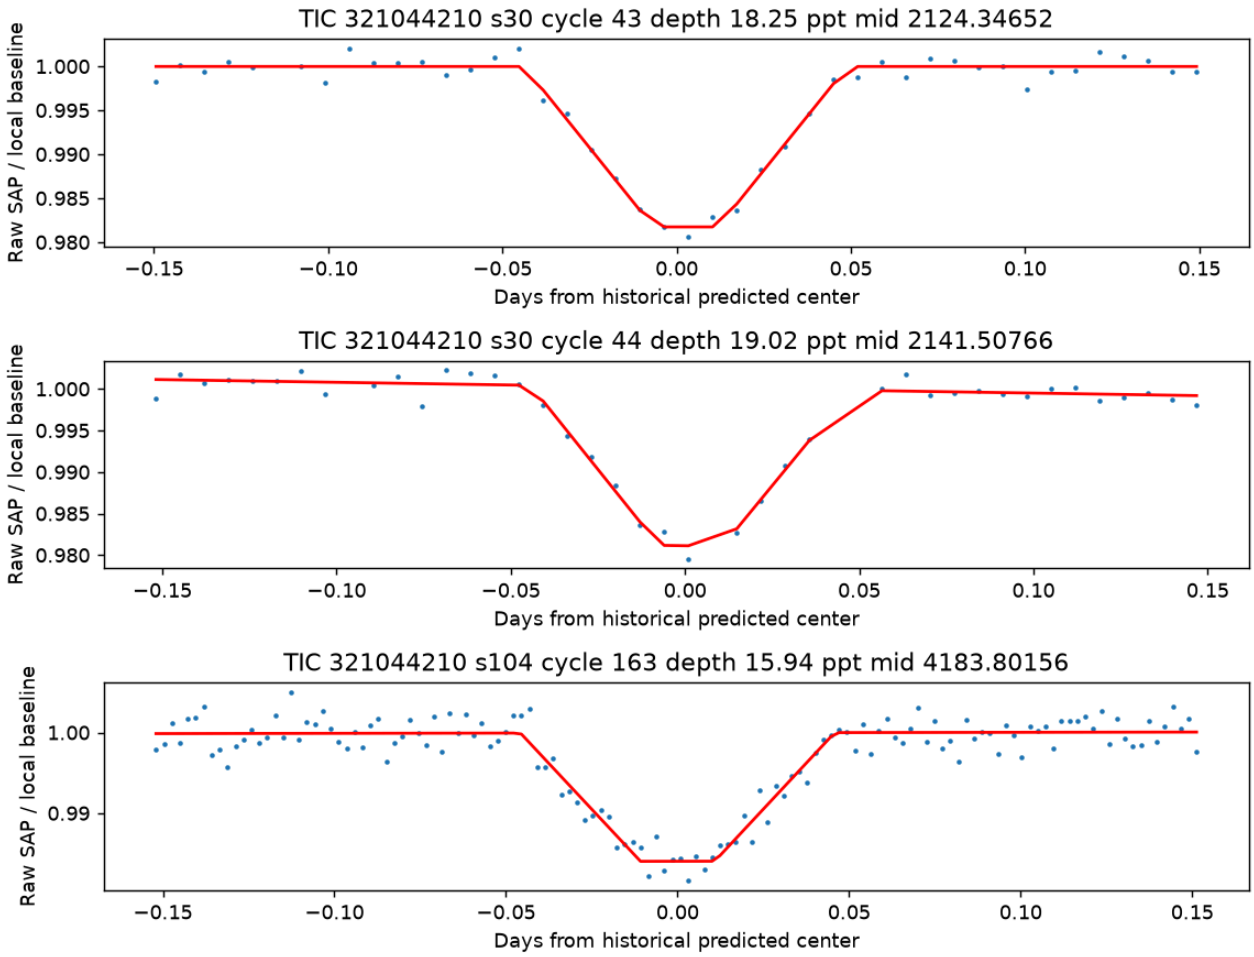
Limitations: Representative same-kind raw eclipses recur within a sector. Photometric period is fitted from measured centers; the historical photometric branch guides extraction. No exhaustive blind alias scan claimed. Depths depend on aperture dilution and local baseline. Pixel centroid uncertainties and timing systematics are not calibrated.

Next check: Optional precision characterization.

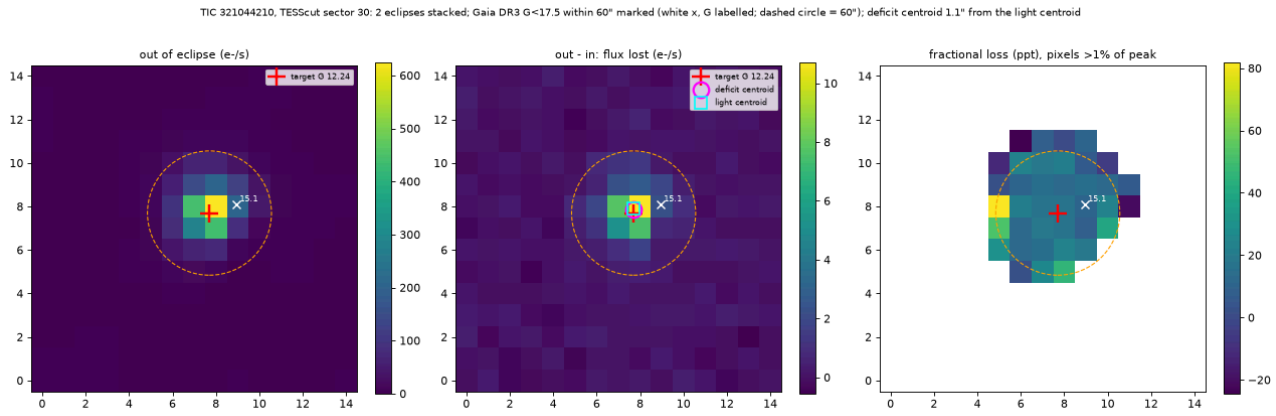
Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-windows.csv, raw-events.png, historical/diff_s30.json; batch alias-audit.json, recurrence-coverage.json, pixel-audit.json, gaia-geometry.json, download-receipts.json and

SHA256SUMS.json. Catalogue novelty is supplied separately by shared-catalogues and does not determine this physical verdict. No claim of exhaustive literature priority.

Stable review key: R333. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R333; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.



R333; diff_s30.png. Target-pixel eclipse-deficit evidence; capable-neighbour and angular-resolution limitations remain in the full report.

Archived source: sanitized report text.

TIC 365325928

CONFIRMED; full_review_completion COMPLETE. The bounded five checks are complete; physical uncertainty is retained separately. Gaia DR3 G=12.087224; inventory G=12.0981.

Raw events and timing: 6 accepted measured centers in sectors [13, 100, 103], cycles [0, 1, 175, 176, 181, 182]. Selected period/separation 13.7834802504 +/- 4.05533e-05 days; epoch BTJD 1665.4741263337 (Selected phase-zero eclipse; deepest primary not assumed). Median QLP raw depth 134.5ppt. Predicted centers only guide windows; timings are fitted centers. Singular or zero-covariance fits are excluded. Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.

Attribution: historical sector13 difference deficit lies 0.040px from target. WCS target identity agrees with Gaia 6629440217910875520; coordinate check 0arcsec. Gaia 6629441038245168000: separation 53.15arcsec, deficit distance 2.550px, required intrinsic fraction 0.339 Intrinsic neighbor eclipse requirements and blended pixel losses have different dilution and are not compared as a veto. Helper inspected target/neighbor image morphology.

Alternative reduction: historical custom TESScut3x3 event depths [144.955, 145.882]ppt. These repeat the eclipse pattern in a separate extraction of the same TESS photons; they are not independent observing occasions.

Gaia geometry: full NSS correlation vector propagated at observed epoch. Gaia P=13.78076072 +/- 0.0018094d, eccentricity 0.4022; nearest edge-on conjunction offset -0.18529d (-0.013446phase), descriptive linear covariance error 0.21673d. Mass function 0.041406solar, approximate central duration 10.42h versus representative measured 8.812h. Duration uses TIC radius and main-sequence minimum-mass companion and is not a fitted physical solution. This supports physical plausibility without an arbitrary sigma veto.

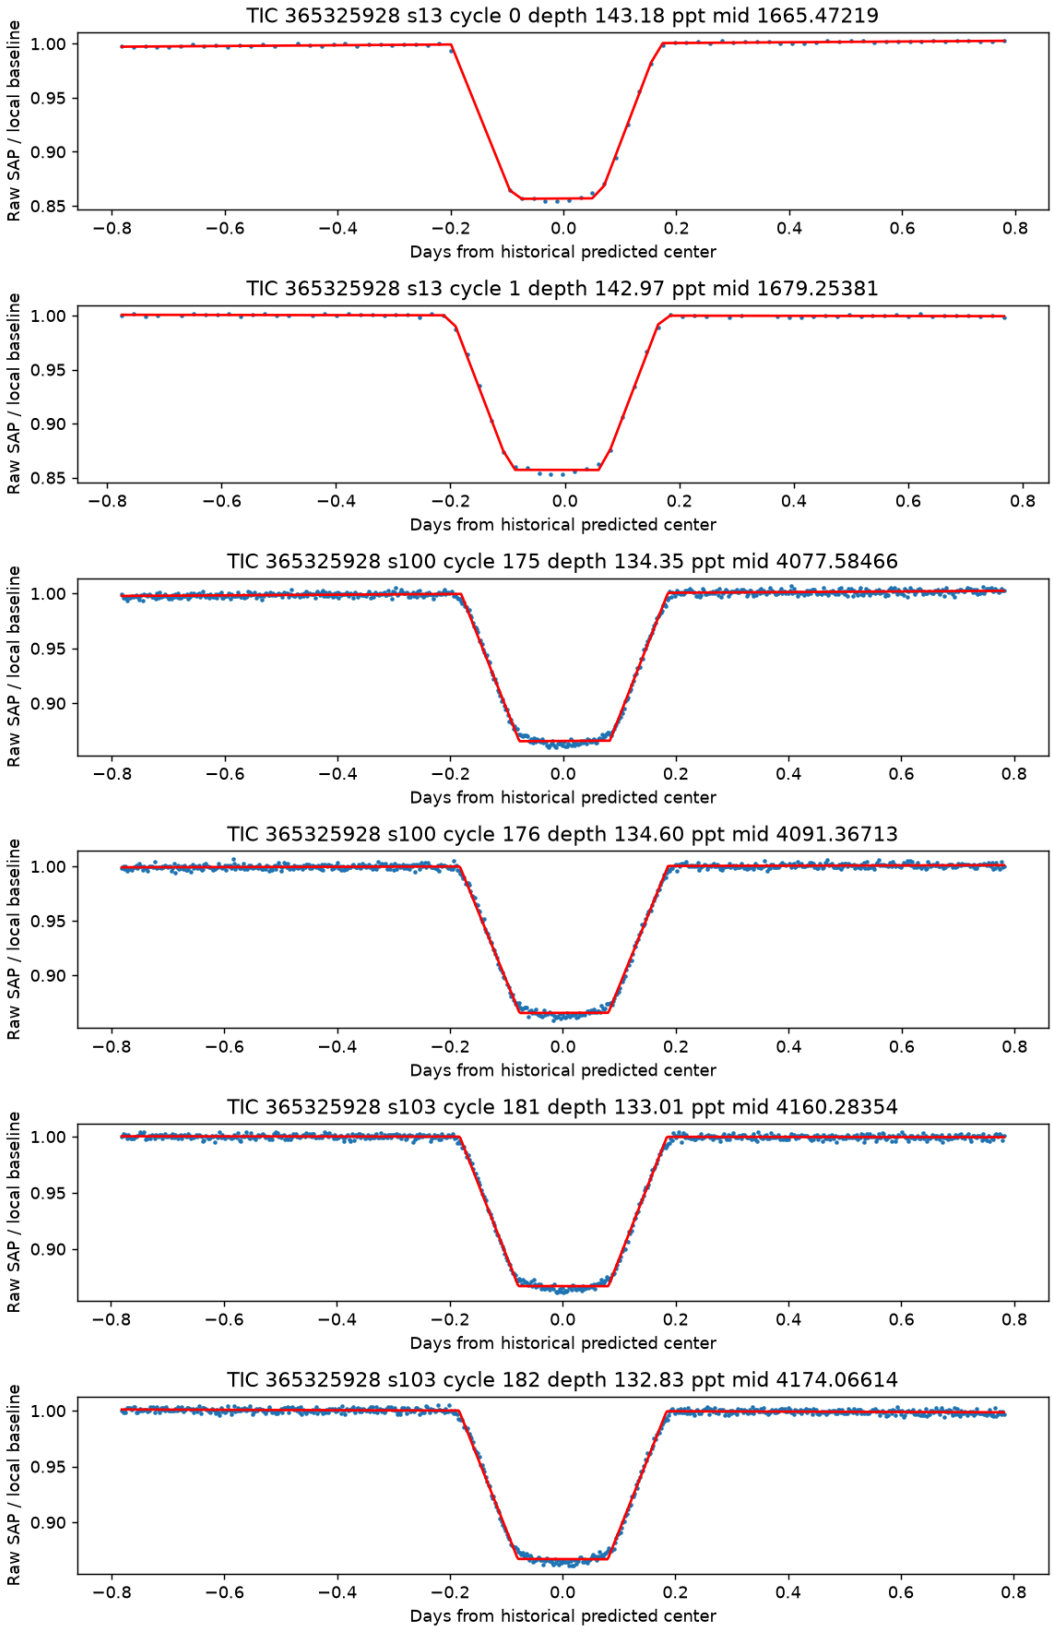
Limitations: Representative same-kind raw eclipses recur within a sector. Photometric period is fitted from measured centers; the historical photometric branch guides extraction. No exhaustive blind alias scan claimed. A distinct secondary occurs near phase.52; it is not mixed into selected-event timings. Depths depend on aperture dilution and local baseline. Pixel centroid uncertainties and timing systematics are not calibrated.

Next check: Optional precision characterization.

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-windows.csv, raw-events.png, historical/diff_s13.json; batch alias-audit.json, recurrence-coverage.json, pixel-audit.json, gaia-geometry.json, download-receipts.json and

SHA256SUMS.json. Catalogue novelty is supplied separately by shared-catalogues and does not determine this physical verdict. No claim of exhaustive literature priority.

Stable review key: R334. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R334; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.

R335. TIC 377129604

physical_verdict: PLAUSIBLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Obtain a third deep eclipse and test same-kind/double aliases

Archived source: sanitized report text.

TIC 377129604

PLAUSIBLE; full_review_completion COMPLETE. The bounded five checks are complete; physical uncertainty is retained separately. Gaia DR3 G=12.135763; inventory G=12.1448.

Raw events and timing: 2 accepted measured centers in sectors [72], cycles [0, 1]. Selected period/separation 18.2332343366 +/- 0.00163699 days; epoch BTJD 3265.4274216896 (First of the two deep S72 events; primary kind unresolved). Median QLP raw depth 55.7ppt. Predicted centers only guide windows; timings are fitted centers. Singular or zero-covariance fits are excluded. Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.

Attribution: historical sector72 difference deficit lies 0.120px from target. WCS target identity agrees with Gaia 3850559470740449920; coordinate check 1.28e-11arcsec. No capable Gaia neighbor within the historical60arcsec list. Intrinsic neighbor eclipse requirements and blended pixel losses have different dilution and are not compared as a veto. Historical image and capable-neighbor numeric audit support target attribution.

Alternative reduction: historical custom TESScut3x3 event depths [46.792, 56.32]ppt. These repeat the eclipse pattern in a separate extraction of the same TESS photons; they are not independent observing occasions.

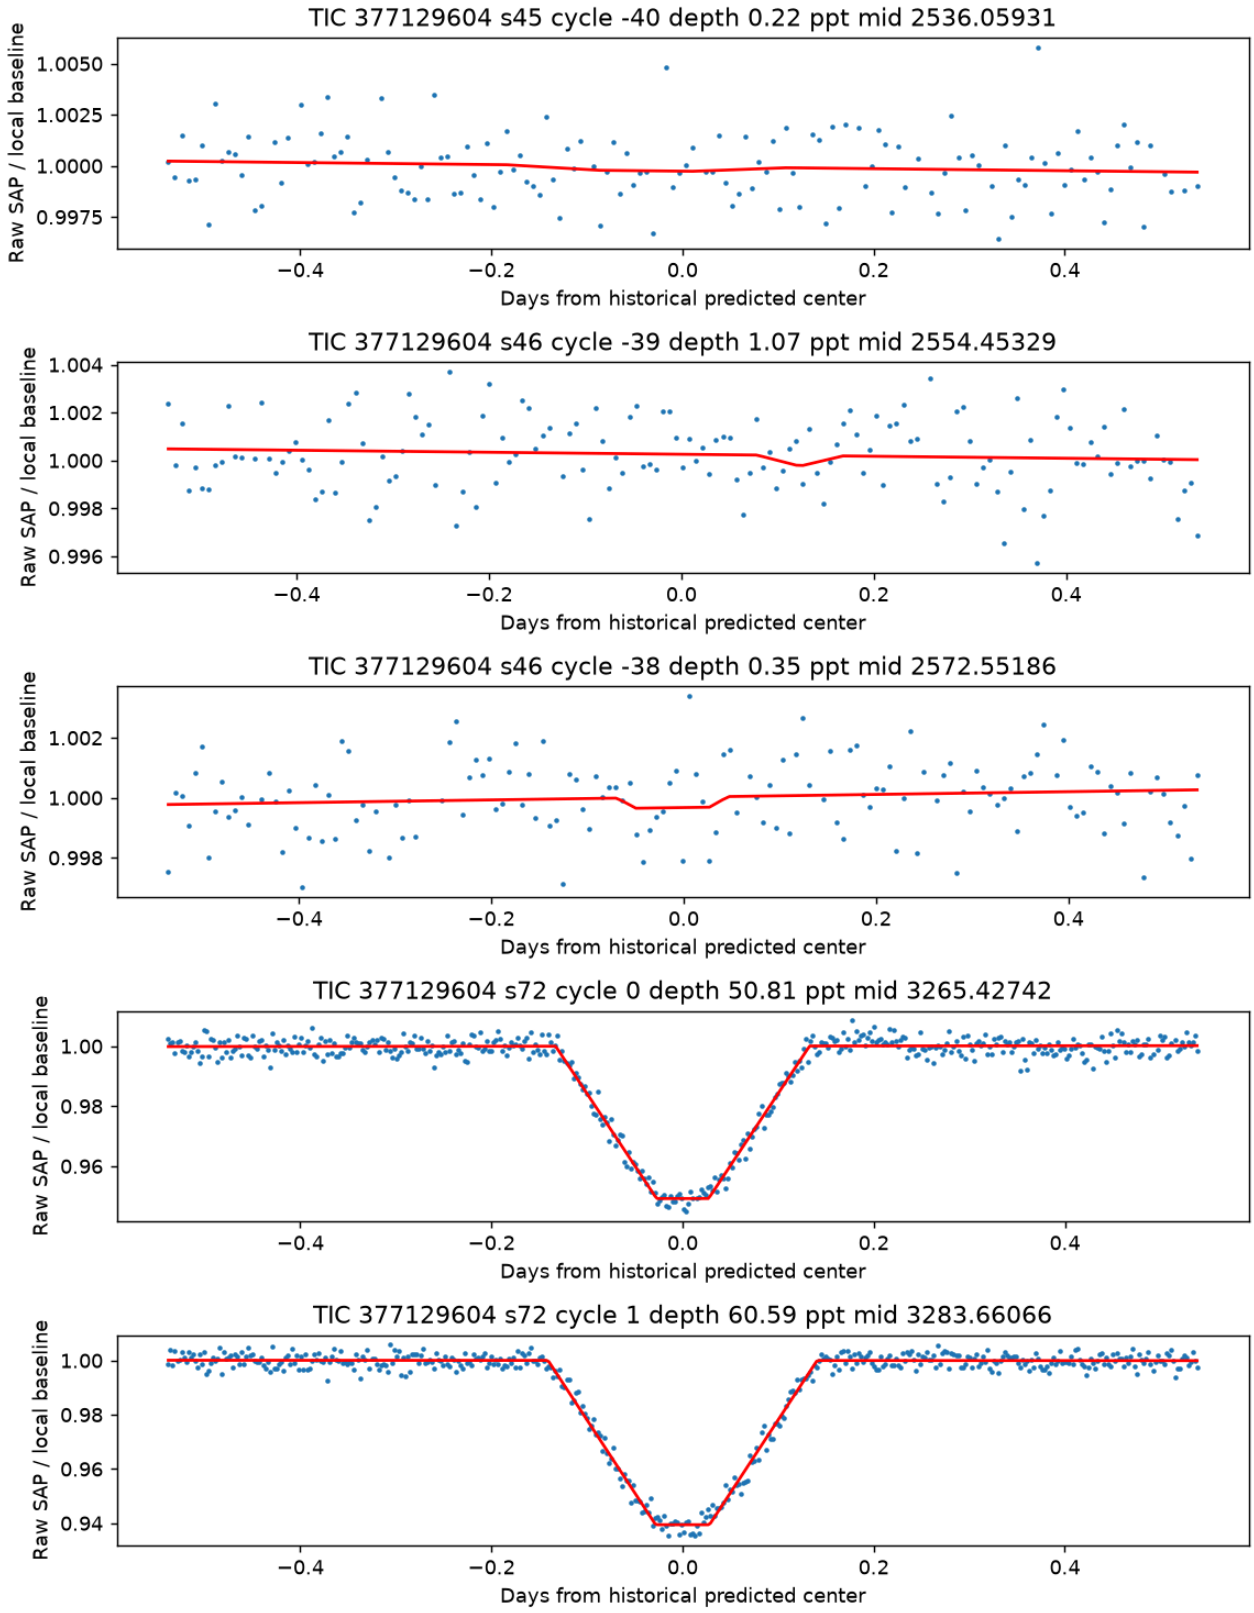
Gaia geometry: full NSS correlation vector propagated at observed epoch. Gaia P=18.24330138 +/- 0.0088054d, eccentricity 0.29798; nearest edge-on conjunction offset 0.6067d (0.033256phase), descriptive linear covariance error 1.3626d. Mass function 0.038711solar, approximate central duration 12.06h versus representative measured 6.567h. Duration uses TIC radius and main-sequence minimum-mass companion and is not a fitted physical solution. Association remains uncertain with the unresolved event period; no arbitrary sigma veto applied.

Limitations: Only two deep S72 events are established. Their depths50.81/60.59ppt differ in QLP and custom aperture. The18.233234d value is a measured event separation, not an established same-kind orbital period;36.466469d double alias and eclipse-kind ambiguity remain. All available QLP sectors45,46,72 were inspected; earlier weak fits excluded, not used as timings. Earlier absence is not asserted as a clean null. Historical18.266535d period is not adopted. Depths depend on aperture dilution and local baseline. Pixel centroid uncertainties and timing systematics are not calibrated.

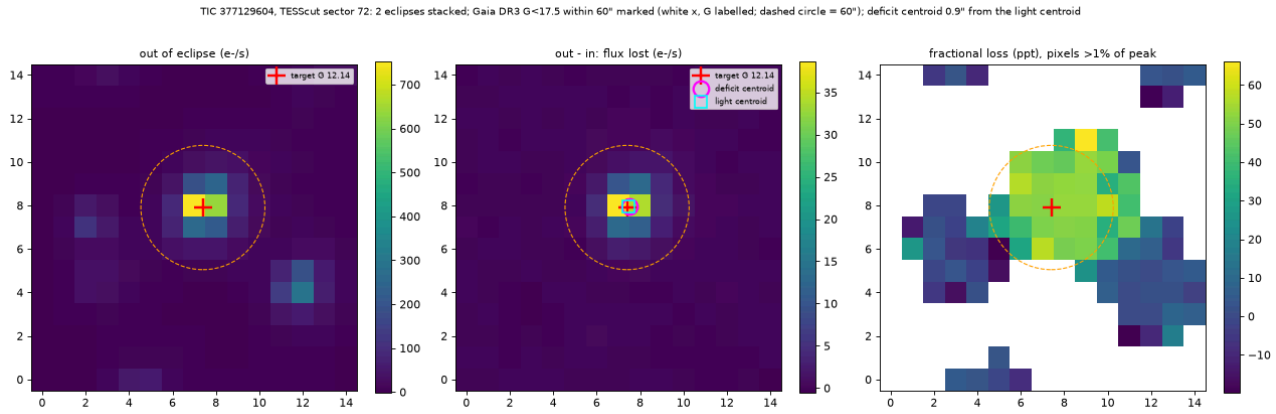
Next check: Obtain a third deep eclipse and test same-kind/double aliases.

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-windows.csv, raw-events.png, historical/diff_s72.json; batch alias-audit.json, recurrence-coverage.json, pixel-audit.json, gaia-geometry.json, download-receipts.json and SHA256SUMS.json. Catalogue novelty is supplied separately by shared-catalogues and does not determine this physical verdict. No claim of exhaustive literature priority.

Stable review key: R335. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R335; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.



R335; diff_s72.png. Target-pixel eclipse-deficit evidence; capable-neighbour and angular-resolution limitations remain in the full report.

R336. TIC 601646479

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolve source with higher-resolution eclipse photometry

Archived source: sanitized report text.

TIC 601646479

PROBABLE; full_review_completion COMPLETE. The bounded five checks are complete; physical uncertainty is retained separately. Gaia DR3 G=12.4559765; inventory G=12.4571.

Raw events and timing: 13 accepted measured centers in sectors [57, 84], cycles [0, 2, 4, 8, 10, 12, 14, 414, 416, 418, 422, 424, 426]. Selected period/separation 3.53584755057 +/- 3.26717e-06 days; epoch BTJD 2855.0542777326 (Deeper alternating eclipse). Median QLP raw depth 73.38ppt. Predicted centers only guide windows; timings are fitted centers. Singular or zero-covariance fits are excluded. Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.

Attribution: historical sector57 difference deficit lies 0.165px from target. WCS target identity agrees with Gaia 393144577378897536; coordinate check 2.12e-12arcsec. Gaia 393144577381887232: separation 1.89arcsec, deficit distance 0.137px, required intrinsic fraction 0.083; Gaia 393144611741629568: separation 54.13arcsec, deficit distance 2.688px, required intrinsic fraction 0.763 Intrinsic neighbor eclipse requirements and blended pixel losses have different dilution and are not compared as a veto. Helper inspected target/neighbor image morphology; the close source remains unresolved.

Alternative reduction: historical custom TESScut3x3 event depths [23.14, 14.397, 21.768, 13.414, 22.951, 23.163, 14.872, 22.965, 14.402, 21.746, 14.247, 22.908, 14.534]ppt. These repeat the eclipse pattern in a separate extraction of the same TESS photons; they are not independent observing occasions.

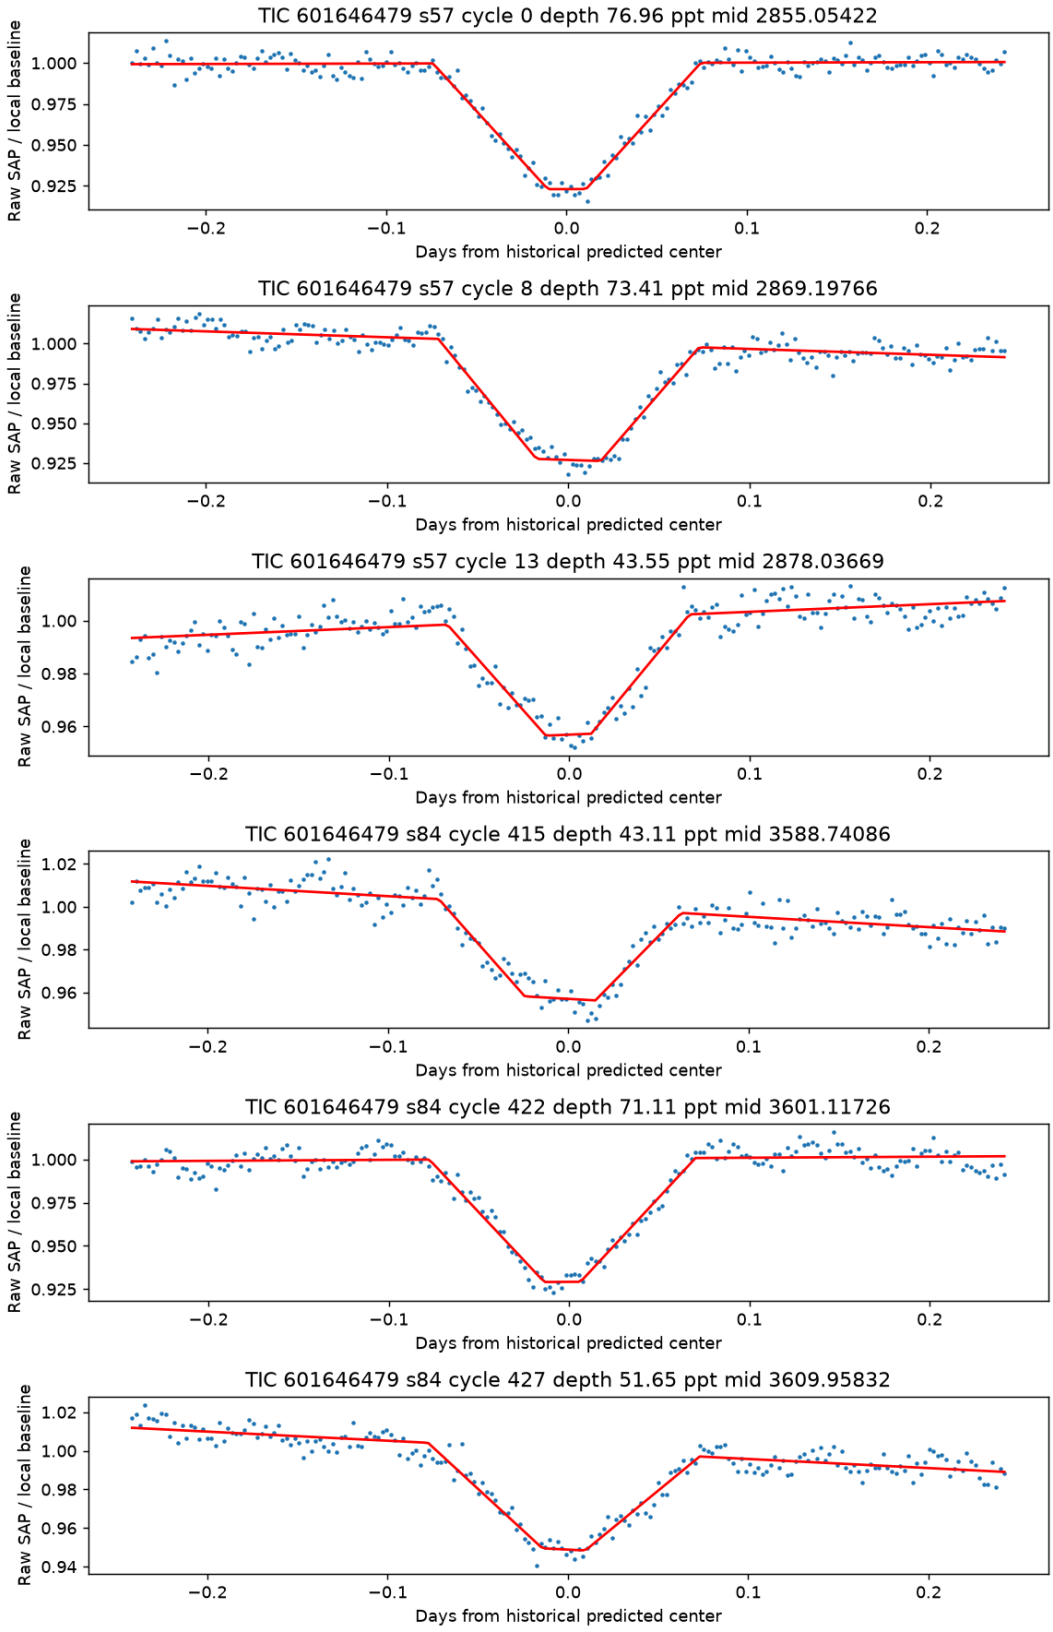
Gaia geometry: full NSS correlation vector propagated at observed epoch. Gaia P=3.535862158 +/- 0.00021477d, eccentricity 0.11456; nearest edge-on conjunction offset 0.084708d (0.023957phase), descriptive linear covariance error 0.15219d. Mass function 0.20385solar, approximate central duration 5.95h versus representative measured 3.485h. Duration uses TIC radius and main-sequence minimum-mass companion and is not a fitted physical solution. This supports physical plausibility without an arbitrary sigma veto.

Limitations: Unequal alternating eclipses establish full3.535848d orbit from13 deeper even historical half-period cycles, orbital_cycle=cycle/2. Attribution remains unresolved against the capable1.89arcsec neighbor; its deficit distance0.137px is slightly smaller than target0.165px. Image cannot resolve these sources. Depths depend on aperture dilution and local baseline. Pixel centroid uncertainties and timing systematics are not calibrated.

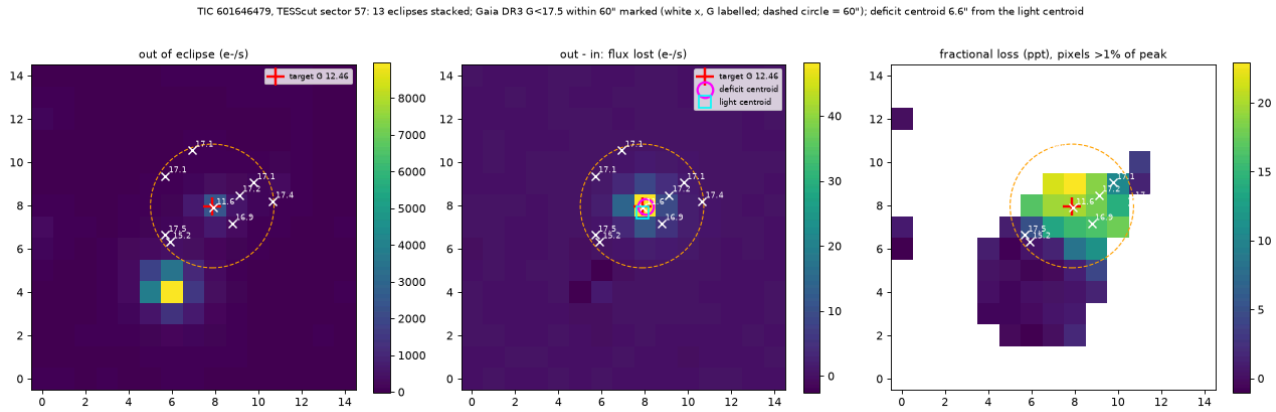
Next check: Resolve source with higher-resolution eclipse photometry.

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-windows.csv, raw-events.png, historical/diff_s57.json; batch alias-audit.json, recurrence-coverage.json, pixel-audit.json, gaia-geometry.json, download-receipts.json and SHA256SUMS.json. Catalogue novelty is supplied separately by shared-catalogues and does not determine this physical verdict. No claim of exhaustive literature priority.

Stable review key: R336. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.



R336; raw-events.png. Representative raw-flux eclipse windows; timing and quality qualifications remain in the full report.



R336; diff_s57.png. Target-pixel eclipse-deficit evidence; capable-neighbour and angular-resolution limitations remain in the full report.

Spectroscopic-orbit period folds: remaining G 11.5-12 evidence

Completion of the bright screened stratum. The remaining 73 screened Gaia spectroscopic-orbit period-fold candidates at actual Gaia DR3 G = 11.5-12 (range 11.6578-11.9967) completed the same bounded review: 69 confirmed, 3 probable and 1 plausible; 72 are eligible unique additions. This follow-up completes that remaining bright stratum and is separate from the fixed balanced 120-target magnitude comparison, whose sample and descriptive results remain unchanged. Historical inventory-boundary exclusions that meet the actual DR3 interval retain their original substitution provenance. No targets were substituted in this follow-up. The remaining screened inventory contains 266 candidates: 90 at G 12-12.25, 96 at G 12.25-12.5 and 80 at G 12.5-12.75. Five weaker conjunction candidates, 58 lower-score candidates and 48 unexecuted exploratory appointment targets are separate populations. These outcomes do not measure blind discovery yield or completeness.

Period, epoch and attribution limits. TIC 16809274 retains a shallower-eclipse reference epoch. TIC 119193784 remains probable because integer-cycle aliases are unresolved; TIC 382631802 remains plausible and excluded because structured variability and broad-model duration tension leave the eclipse interpretation insecure; the pixel evidence favours the target. TIC 343340931 and TIC 363264601 remain probable because capable neighbours prevent definitive attribution. The equal-depth aliases of TIC 76020303 and TIC 168917716 are Gaia-informed interpretations; their eclipse timing uncertainties do not resolve the orbital half/double ambiguity. Full reports preserve measured event centers, quality flags, error meanings and source-specific limitations.

R337. TIC 135362193

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 135362193: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 7 distinct eclipse events in selected sectors[53, 80]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=4.6690140750 Ã‚±0.0000131496d, reference eclipse epoch BTJD2745.7473584, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S79 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation2.323arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.232. Capable neighbours: Gaia 4577603498730811008: 18.91 arcsec, G16.165, required fractional eclipse0.691; Gaia 4577603498730962560: 22.88 arcsec, G14.835, required fractional eclipse0.211
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths10.151/10.284/10.166ppt, with 4 stacked events. QLP selected-kind fitted median11.442ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3457603498730812672, P=4.6688816715Ã‚±0.0002208323d, e=0.038599, omega=117.5167deg. Closest edge-on conjunction offset0.046153d (0.009885phase), full-SB1-covariance linear propagated Gaia uncertainty0.103629d at the measured epoch. Near-Gaia-reference projected eclipse offset-

0.020711d (photometric period projection allowance0.006641d). The approximate central duration5.44h vs observed median2.09h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Shallow repeated eclipses across sectors53/80; capable neighbors at18.9/22.9arcsec lie0.91/1.06pixel from deficit versus target0.11pixel. Target-centered core supports attribution at TESS resolution; no calibrated localization errors. Sector80 pipeline offsets remain systematic uncertainty.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
53	157	2745.7456293	0.003472	11.442	used in ephemeris

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 346865542: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 4 distinct eclipse events in selected sectors[42, 43, 70]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=12.0441549925 Ã‚±0.0000365340d, reference eclipse epoch BTJD2449.5432269, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S42 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation0.666arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.080. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths60.315/59.572/57.677ppt, with 2 stacked events. QLP selected-kind fitted median67.432ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3256456430589727488, P=12.0444654688Ã‚±0.0006823424d, e=0.460253, omega=166.0696deg. Closest edge-on conjunction offset-0.081524d (-0.006769phase), full-SB1-covariance linear propagated Gaia uncertainty0.149158d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.028433d (photometric period projection allowance0.006247d). The approximate central

duration6.28h vs observed median3.82h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four deep isolated eclipses test within-sector recurrence and long-baseline cycle count. Aperture dilution retained; fitted depths are not intrinsic.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 131331287: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 8 distinct eclipse events in selected sectors[37, 64, 102]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=6.8447853694 Ã‚±0.0000054333d, reference eclipse epoch BTJD2313.5253293, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S64 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation1.201arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.046. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths121.693/118.758/116.981ppt, with 3 stacked events. QLP selected-kind fitted median135.367ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3616982634869970342 4, P=6.8443655076Ã‚±0.0009405552d, e=0.259533, omega=305.2292deg. Closest edge-on conjunction offset0.053274d (0.007784phase), full-SB1-covariance linear propagated Gaia uncertainty0.199939d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.064708d (photometric period projection allowance0.001527d). The approximate central

duration6.94h vs observed median5.70h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated events have reduced depths in sector102 relative to37/64; aperture dilution or baseline changes possible, no intrinsic depth variation claimed.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
37	0	2313.5221586	0.003472	135.542	used in ephemeris

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 48752905: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 52 distinct eclipse events in selected sectors[33, 87]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 25 same-kind midtimes give P=1.7220909305 Ã‚±0.0000011993d, reference eclipse epoch BTJD2202.7901470, kind: Deeper repeating eclipse; even half-period cycles. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S33 deficit peak[8, 8] vs target pixel[7, 8]; deficit-target separation1.683arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.221. Capable neighbours: Gaia 2926491213995591296: 40.26 arcsec, G15.750, required fractional eclipse0.855; Gaia 2926491351434540160: 40.72 arcsec, G13.776, required fractional eclipse0.155; Gaia 2926491042196899200: 47.18 arcsec, G15.412, required fractional eclipse0.632
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths25.065/24.019/21.698ppt, with 28 stacked events. QLP selected-kind fitted median37.566ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR32926491244053139712, P=1.7220692438Ã‚±0.0000166135d, e=0.015301, omega=141.9089deg. Closest edge-on conjunction offset0.026703d (0.015506phase), full-SB1-covariance linear propagated Gaia uncertainty0.018956d at the measured epoch. Near-Gaia-reference projected eclipse

offset0.003867d (photometric period projection allowance0.001263d). The approximate central duration4.35h vs observed median2.24h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipses establish doubled period relative to historical SAP half-period. Deeper even historical cycles alone define epoch and orbital timing; mixed historical cutout stack is not a same-kind depth measurement.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 337881909: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 9 distinct eclipse events in selected sectors[13, 93, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 9 same-kind midtimes give P=9.6174021260 Ã‚±0.0000203371d, reference eclipse epoch BTJD1661.0486137, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S13 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation1.252arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.828. Capable neighbours: Gaia 6724638855242197120: 17.77 arcsec, G14.446, required fractional eclipse0.193; Gaia 6724638820882453888: 21.65 arcsec, G16.246, required fractional eclipse0.952; Gaia 6724638889601940224: 21.89 arcsec, G15.135, required fractional eclipse0.351; Gaia 6724638820882457984: 26.79 arcsec, G15.128, required fractional eclipse0.349; Gaia 6724638923961681280: 27.11 arcsec, G15.629, required fractional eclipse0.545; Gaia 6724638820882447232: 47.87 arcsec, G16.037, required fractional eclipse0.788; Gaia 6724638850925800064: 52.52 arcsec, G16.080, required fractional eclipse0.819; Gaia 6724638649083749760: 58.15 arcsec, G15.084, required fractional eclipse0.336
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths13.705/13.040/11.404ppt, with 3 stacked events. QLP selected-kind fitted median13.400ppt. This separately extracted cutout is an alternative reduction of the same TESS

photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3672463888528215872O, P=9.6159030557Ã‚±0.0037502071d, e=0.245757, omega=215.8197deg. Closest edge-on conjunction offset0.007154d (0.000744phase), full-SB1-covariance linear propagated Gaia uncertainty0.532172d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.190723d (photometric period projection allowance0.002684d). The approximate central duration9.33h vs observed median8.77h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Crowded field: eight capable neighbors, nearest17.8arcsec; deficit0.06pixel from target versus0.80pixel from nearest capable source. Target-centered core favors target, but highPSF fractional residual0.83 limits precise localization. No calibrated errors or resolved binary parameters claimed.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.412. Capable neighbours: Gaia 1413834278144873728: 28.85 arcsec, G12.494, required fractional eclipse0.138
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths37.663/31.396/28.856ppt, with 2 stacked events. QLP selected-kind fitted median45.643ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR31413834312504612352, P=12.9670803122Ã‚±0.0021571855d, e=0.248242, omega=61.1714deg. Closest edge-on conjunction offset0.089513d (0.006903phase), full-SB1-covariance linear propagated Gaia uncertainty0.291273d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.003301d (photometric period projection allowance0.004295d). The approximate central

duration6.01h vs observed median3.94h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Same-kind repeat within sector53 and84 secures long-baseline cycle count. Modest aperture/sector depth differences retained.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
23	0	1931.6472336	0.010417	41.906	used in ephemeris
53	63	2748.6237263	0.003472	45.643	used in ephemeris

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 14291901: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 11 distinct eclipse events in selected sectors[42, 44, 71]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=5.9988293272 Ã‚±0.0000112890d, reference eclipse epoch BTJD2448.4020518, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S43 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation0.978arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.047. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths40.282/39.535/39.267ppt, with 3 stacked events. QLP selected-kind fitted median43.443ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3502219158807322 88, P=5.9990825867Ã‚±0.0004188713d, e=0.004308, omega=257.5851deg. Closest edge-on conjunction offset-0.108901d (-0.018153phase), full-SB1-covariance linear propagated Gaia uncertainty0.155500d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.022033d (photometric period projection allowance0.003872d). The approximate central

duration4.74h vs observed median2.89h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated eclipses at multiple successive cycles; Gaia conjunction offset retained with propagated orbit covariance and radius/model limitations.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 180179209: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 9 distinct eclipse events in selected sectors[11, 65, 101]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=6.3122615616 Ã‚±0.0000079776d, reference eclipse epoch BTJD1601.6364849, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S64 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation4.874arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.815. Capable neighbours: Gaia 6054997992860786816: 16.65 arcsec, G14.888, required fractional eclipse0.454; Gaia 6054997997204150784: 28.39 arcsec, G14.393, required fractional eclipse0.296; Gaia 6054997962844403840: 34.00 arcsec, G15.410, required fractional eclipse0.722; Gaia 6054997928484667904: 34.34 arcsec, G14.207, required fractional eclipse0.253; Gaia 6054998164658275584: 35.63 arcsec, G12.723, required fractional eclipse0.081; Gaia 6054997924140107776: 37.07 arcsec, G14.060, required fractional eclipse0.224; Gaia 6054997928484660992: 40.14 arcsec, G14.685, required fractional eclipse0.381; Gaia 6054997928484659200: 41.13 arcsec, G14.017, required fractional eclipse0.216; Gaia 6054997928484664704: 42.76 arcsec, G15.405, required fractional eclipse0.718; Gaia 6054998233379003392: 54.73 arcsec, G15.640, required fractional eclipse0.887; Gaia 6054998164659490560: 59.57 arcsec, G15.708, required fractional eclipse0.942

4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths23.099/18.880/11.766ppt, with 4 stacked events. QLP selected-kind fitted median24.572ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3605499799285958412 8, P=6.3121869210Ã‚,+/-0.0008826224d, e=0.294949, omega=289.1618deg. Closest edge-on conjunction offset0.000128d (0.000020phase), full-SB1-covariance linear propagated Gaia uncertainty0.168798d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.014203d (photometric period projection allowance0.001532d). The approximate central duration7.03h vs observed median5.45h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Crowded field: eleven capable neighbors, nearest16.6arcsec; deficit0.23pixel from target versus1.00pixel from nearest capable source. PSF residual0.82 limits localization precision; target-centered core supports attribution at TESS resolution. Final partial/singular sector101 fit excluded from timing.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
11	0	1601.6392042	0.010417	23.608	used in ephemeris
11	1	1607.9484964	0.010417	22.568	used in ephemeris

R344; diff_s64.png. Target-pixel eclipse-deficit evidence. The full report retains capable-neighbour and angular-resolution qualifications.

R345. TIC 351335839

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 351335839: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 8 distinct eclipse events in selected sectors[13, 101, 104]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=14.8399513286 Ã‚±0.0000448985d, reference eclipse epoch BTJD1655.6300072, kind: Deeper repeating eclipse; even half-period cycles. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S13 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.874arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.992. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths284.455/267.314/185.501ppt, with 4 stacked events. QLP selected-kind fitted median380.798ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR36444110588084162688, P=14.8359991883Ã‚±0.0022444509d, e=0.037964, omega=230.7166deg. Closest edge-on conjunction offset0.190357d (0.012831phase), full-SB1-covariance linear propagated Gaia uncertainty0.212663d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.145575d (photometric period projection allowance0.003816d). The approximate central duration7.04h vs observed median5.25h permits noncentral geometry; this radius/minimum-mass

estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipse depths establish doubled orbital period; deeper even historical cycles define ephemeris. Initial duration bound broadened to capture deepV morphology. Poor PSF residual0.99 limits detailed image modeling, but target-centered deficit and no capable listed neighbors support source. Mixed historical cutout stack cannot be equated to primary depth.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 89553209: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 6 distinct eclipse events in selected sectors[14, 54, 81]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=11.8658638287 Ã‚±0.0000359636d, reference eclipse epoch BTJD1695.6867422, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S14 deficit peak[8, 7] vs target pixel[7, 8]; deficit-target separation0.970arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.476. Capable neighbours: Gaia 2024239325242611072: 53.46 arcsec, G14.018, required fractional eclipse0.461
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths10.283/12.097/12.528ppt, with 2 stacked events. QLP selected-kind fitted median51.272ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR32024239325242612736, P=11.8678248503Ã‚±0.0035823200d, e=0.375346, omega=266.7319deg. Closest edge-on conjunction offset-0.231422d (-0.019500phase), full-SB1-covariance linear propagated Gaia uncertainty0.480204d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.015709d (photometric period projection allowance0.003956d). The approximate central

duration12.04h vs observed median11.52h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Sector14 cycle-1 lacks ingress coverage and is excluded from timing. Remaining five measured events include successive sector54/81 pairs and a full sector14 event. Historical prediction drift is fitted freely; partial raw event is not a precise timing. Broad eclipse duration and radius-based central estimate agree approximately.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
14	-1	1683.8202443	0.010417	50.113	Partially covered eclipse lacks ingress baseline; retained raw morphology but excluded timing.
14	0	1695.6905685	0.010417	51.272	used in ephemeris

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 60555220: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors[7, 35, 88]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=8.4552418596 ±0.0000133662d, reference eclipse epoch BTJD1498.9281820, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S7 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation2.023arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.712. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths225.863/215.449/147.434ppt, with 3 stacked events. QLP selected-kind fitted median258.330ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3551210285665213 2736, P=8.4559112267±0.0006208254d, e=0.016619, omega=326.8573deg. Closest edge-on conjunction offset-0.021730d (-0.002570phase), full-SB1-covariance linear propagated Gaia uncertainty0.089100d at the measured epoch. Near-Gaia-reference projected eclipse offset0.065957d (photometric period projection allowance0.001751d). The approximate central

duration5.52h vs observed median4.28h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Representative raw eclipses recur. Depths remain diluted and sector dependent; timing errors omit uncalibrated extraction and shape systematics.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R348. TIC 142932503

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 142932503: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 3 distinct eclipse events in selected sectors[14, 47, 75]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=18.6886141507 ±0.0000723224d, reference eclipse epoch BTJD1699.2030487, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json; for142932503 the three separated centers, integer-count scan and clean submultiple tests are in helper/alias142.py and helper audit. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S14 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.808arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.433. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths154.268/153.320/151.562ppt, with 1 stacked events. QLP selected-kind fitted median170.639ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3106167066809147648O, P=18.6878640883±0.0038143874d, e=0.507144, omega=148.4350deg. Closest edge-on conjunction offset0.027089d (0.001450phase), full-SB1-covariance linear propagated Gaia uncertainty0.325945d

at the measured epoch. Near-Gaia-reference projected eclipse offset-0.025415d (photometric period projection allowance0.005063d). The approximate central duration5.60h vs observed median4.19h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Three separated measured eclipses at cycles0,48,89. Independent integer-count scan1-25d finds unique near18.69d fit; clean sector47 nulls reject identical deep events at divisors2,3,4. This is bounded alias evidence, not exhaustive all-period exclusion.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 256260982: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 16 distinct eclipse events in selected sectors[26, 53, 80]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 16 same-kind midtimes give P=3.2856228182 ±0.0000056568d, reference eclipse epoch BTJD2031.8784385, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S40 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.022arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.197. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths145.050/142.465/141.179ppt, with 5 stacked events. QLP selected-kind fitted median173.195ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3452540572608998 4184, P=3.2853698535±0.0001679014d, e=0.050016, omega=131.5130deg. Closest edge-on conjunction offset0.076348d (0.023239phase), full-SB1-covariance linear propagated Gaia uncertainty0.114725d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.050134d (photometric period projection allowance0.002828d). The approximate central duration4.50h vs observed median4.07h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Representative raw eclipses recur. Depths remain diluted and sector dependent; timing errors omit uncalibrated extraction and shape systematics.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Archived source: sanitized report text.

TIC 11176109: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 13 distinct eclipse events in selected sectors[7, 61, 88]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 13 same-kind midtimes give P=5.0191531715 ±0.0000048262d, reference eclipse epoch BTJD1501.3234240, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S61 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation2.987arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.565. Capable neighbours: Gaia 5713502188219216384: 16.97 arcsec, G13.638, required fractional eclipse0.762; Gaia 5713502089440751232: 35.79 arcsec, G12.303, required fractional eclipse0.300; Gaia 5713501917642055808: 59.41 arcsec, G13.219, required fractional eclipse0.553
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths100.668/77.592/55.934ppt, with 4 stacked events. QLP selected-kind fitted median110.415ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3571350212380031168, P=5.0189270961±0.0003204633d, e=0.059916, omega=184.1156deg. Closest edge-on conjunction offset-0.004499d (-0.000896phase), full-SB1-covariance linear propagated Gaia

uncertainty0.078599d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.054687d (photometric period projection allowance0.001071d). The approximate central duration4.36h vs observed median3.88h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated eclipses. Target0.142pixel from deficit versus nearest capable neighbor0.722pixel, which would require76percent intrinsic loss. Target favored by concentrated deficit core, without calibrated localization uncertainty.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 279823568: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[21, 47]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=4.4197074796 ±0.0000283837d, reference eclipse epoch BTJD1873.6000620, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S21 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation5.456arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.069. Capable neighbours: Gaia 1012826405920802560: 45.32 arcsec, G16.425, required fractional eclipse0.927
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths12.160/11.633/11.566ppt, with 6 stacked events. QLP selected-kind fitted median11.191ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3101282620405770060 8, P=4.4200216973±0.0006874443d, e=0.100927, omega=16.0548deg. Closest edge-on conjunction offset0.027673d (0.006261phase), full-SB1-covariance linear propagated Gaia uncertainty0.264185d at the measured epoch. Near-Gaia-reference projected eclipse offset0.133250d (photometric period projection allowance0.009537d). The approximate central duration5.27h vs observed median5.65h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Representative raw eclipses recur. Depths remain diluted and sector dependent; timing errors omit uncalibrated extraction and shape systematics.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 220617848: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 5 distinct eclipse events in selected sectors[32, 33]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=9.9217119096 ±0.0009025586d, reference eclipse epoch BTJD2177.2176816, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S33 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.858arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.355. Capable neighbours: Gaia 4802940366659639808: 46.36 arcsec, G15.176, required fractional eclipse0.849
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths33.374/31.962/30.168ppt, with 3 stacked events. QLP selected-kind fitted median36.320ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3480293998440533593 6, P=9.9222605876±0.0022063493d, e=0.263062, omega=113.6466deg. Closest edge-on conjunction offset-0.117564d (-0.011849phase), full-SB1-covariance linear propagated Gaia uncertainty0.384956d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.018802d (photometric period projection allowance0.162461d). The approximate central

duration3.56h vs observed median2.43h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Representative raw eclipses recur. Depths remain diluted and sector dependent; timing errors omit uncalibrated extraction and shape systematics.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

R354. TIC 254723054

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 254723054: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 7 distinct eclipse events in selected sectors[12, 65, 103]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=13.8861420099 ±0.0000226421d, reference eclipse epoch BTJD1636.3604759, kind: Deeper repeating eclipse; even half-period cycles. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S65 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.094arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.384. Capable neighbours: Gaia 5987885181823038720: 19.91 arcsec, G14.701, required fractional eclipse0.629
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths24.441/23.551/24.559ppt, with 3 stacked events. QLP selected-kind fitted median40.985ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3598788514313164928O, P=13.8892341157±0.0021777940d, e=0.042019, omega=326.0764deg. Closest edge-on conjunction offset-0.077217d (-0.005560phase), full-SB1-covariance linear propagated Gaia uncertainty0.194146d at the measured epoch. Near-Gaia-reference projected eclipse offset0.201072d (photometric period projection allowance0.002038d). The approximate central duration13.11h vs

observed median12.03h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Stable alternating depths establish doubled orbital period. Four deeper even historical half-period events alone define ephemeris; historical cutout stack mixes both kinds. Nearest capable neighbor is0.883pixel from deficit versus target0.100pixel; target favored at image resolution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 257483992: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 8 distinct eclipse events in selected sectors[3, 30, 97]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=8.7868298591 ±0.0000112166d, reference eclipse epoch BTJD1392.1739129, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S97 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation1.034arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.084. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths21.166/21.235/20.570ppt, with 4 stacked events. QLP selected-kind fitted median18.882ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3514769553608211635 2, P=8.7875714993±0.0016554215d, e=0.153182, omega=203.5610deg. Closest edge-on conjunction offset-0.112963d (-0.012855phase), full-SB1-covariance linear propagated Gaia uncertainty0.222418d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.028416d (photometric period projection allowance0.001279d). The approximate central

duration7.97h vs observed median6.42h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Representative raw eclipses recur. Depths remain diluted and sector dependent; timing errors omit uncalibrated extraction and shape systematics.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Updated spectroscopy to test Gaia ephemeris tension

Archived source: sanitized report text.

TIC 388052602: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 21 distinct eclipse events in selected sectors[46, 88]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 10 same-kind midtimes give P=4.5139686736 ±0.0000064790d, reference eclipse epoch BTJD2552.6908935, kind: Deeper repeating eclipse; odd half-period cycles. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S46 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.269arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.546. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths64.003/63.122/58.832ppt, with 11 stacked events. QLP selected-kind fitted median97.691ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3314714969430761408O, P=4.5134701102±0.0001857166d, e=0.019114, omega=5.4854deg. Closest edge-on conjunction offset0.307071d (0.068034phase), full-SB1-covariance linear propagated Gaia uncertainty0.101429d at the measured epoch. Near-Gaia-reference projected eclipse offset0.068259d (photometric period projection allowance0.003103d). The approximate central duration5.61h vs observed median3.48h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Stable alternating depths establish doubled orbital period. Ten deeper odd historical half-period events alone define ephemeris; historical cutout stack mixes both kinds. Gaia conjunction offset0.307d (0.068phase) exceeds the linear propagated0.101d error, but near-reference projected offset is0.06826d with independently propagated Gaia uncertainty0.02888d (about2.36 descriptive sigma) and the measured period differs from Gaia by0.000499d. Independent helper geometry388.py finds about3.03 descriptive sigma at the observed epoch. These are linear model uncertainties, not calibrated total coverage. Period accumulation explains much of the distant-epoch offset; low-eccentricity omega/periastron are strongly correlated. This association tension is retained without a sigma veto; updated spectroscopy would test it. Mass function0.126solar and approximate central duration5.61h versus observed3.48h admit noncentral binary geometry.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 157850336: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 4 distinct eclipse events in selected sectors[14, 81]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=14.9033560025 Ã‚±0.0000664269d, reference eclipse epoch BTJD1683.7854476, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S14 deficit peak[8, 1] vs target pixel[7, 7]; deficit-target separation1.384arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.981. Capable neighbours: Gaia 2098520337930119552: 51.05 arcsec, G15.628, required fractional eclipse0.622
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths17.846/16.645/13.145ppt, with 2 stacked events. QLP selected-kind fitted median17.411ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR32098520303570374016, P=14.9046473566Ã‚±0.0047076703d, e=0.280777, omega=94.9536deg. Closest edge-on conjunction offset-0.095974d (-0.006439phase), full-SB1-covariance linear propagated Gaia uncertainty0.356126d at the measured epoch. Near-Gaia-reference projected eclipse offset0.016374d (photometric period projection allowance0.005779d). The approximate central duration6.79h vs

observed median6.90h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated eclipses and successive raw cycles secure recurrence; target deficit0.066pixel versus capable neighbor2.53pixels. Aperture dilution retained.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 233462817: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 4 distinct eclipse events in selected sectors[49, 77]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=10.1615169478 Ã‚±0.0000405203d, reference eclipse epoch BTJD2644.8490471, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S49 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation11.160arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.554. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths3.174/2.700/2.949ppt, with 2 stacked events. QLP selected-kind fitted median3.817ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3151269294914610752O, P=10.1598188069Ã‚±0.0010289917d, e=0.023474, omega=64.8980deg. Closest edge-on conjunction offset0.416191d (0.040964phase), full-SB1-covariance linear propagated Gaia uncertainty0.245151d at the measured epoch. Near-Gaia-reference projected eclipse offset0.039204d (photometric period projection allowance0.008996d). The approximate central duration5.89h vs

observed median1.49h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Shallow repeated raw eclipses in sectors49/77; no capable listed neighbor. Deficit centroid0.53pixel offset and noisy difference image limit precise localization. Gaia conjunction offset0.041phase is interpreted with full covariance (0.245d), short observed duration allowing noncentral geometry; no arbitrary sigma veto.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

R359. TIC 48870240

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 48870240: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 6 distinct eclipse events in selected sectors[91]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=2.7256354375 Ã‚±0.0001582455d, reference eclipse epoch BTJD3777.6561442, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S91 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.173arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.595. Capable neighbours: Gaia 6248866704865905536: 29.16 arcsec, G11.866, required fractional eclipse0.079
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths32.789/20.566/17.718ppt, with 7 stacked events. QLP selected-kind fitted median37.000ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3624886632260882124 8, P=2.7257434900Ã‚±0.0002657921d, e=0.047898, omega=356.3095deg. Closest edge-on conjunction offset-0.069254d (-0.025408phase), full-SB1-covariance linear propagated Gaia uncertainty0.334151d at the measured epoch. Near-Gaia-reference projected eclipse offset0.065055d (photometric period projection allowance0.196699d). The approximate central duration4.18h vs

observed median3.87h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Six measured raw events in sector91 include four successive cycles5-8 and the cycle0/1 pair, establishing recurrence. Capable neighbor1.39pixels from deficit versus target0.056pixel; target core favors attribution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 178199444: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 3 distinct eclipse events in selected sectors[31]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=6.5485022540 Ã‚±0.0016073438d, reference eclipse epoch BTJD2149.2179543, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S31 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation1.857arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.964. Capable neighbours: Gaia 5087572522289602944: 59.59 arcsec, G14.889, required fractional eclipse0.700
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths36.052/32.012/21.556ppt, with 4 stacked events. QLP selected-kind fitted median40.179ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3508757262536881689 6, P=6.5478351785Ã‚±0.0003587164d, e=0.006130, omega=71.8319deg. Closest edge-on conjunction offset-0.031815d (-0.004859phase), full-SB1-covariance linear propagated Gaia uncertainty0.111501d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.211258d (photometric period projection allowance0.432375d). The approximate central duration4.44h vs

observed median2.31h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Three raw events in sector31 include consecutive cycles110/111 and a two-cycle separation108/110. Single selected sector supplies repeated cycles; this is not a single-event case.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
31	108	2149.2174819	0.003472	40.179	used in ephemeris
31	110	2162.3163759	0.003472	40.647	used in ephemeris
31	111	2168.8625163	0.003472	39.168	used in ephemeris

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, shared-qlp QLP FITS; historical/diff_s31.json, historical/diff_s31.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R360. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.

Direct public evidence: measured events, raw eclipse plots, raw flux windows, Gaia geometry, independent audit, difference image.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 375058760: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 9 distinct eclipse events in selected sectors[1, 36, 98]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=7.1293749205 Ã‚±-0.0000079011d, reference eclipse epoch BTJD1329.2625675, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S97 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.295arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.055. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths392.706/389.647/379.041ppt, with 6 stacked events. QLP selected-kind fitted median393.515ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3547872223768323046 4, P=7.1284859943Ã‚±-0.0003946301d, e=0.021598, omega=6.5168deg. Closest edge-on conjunction offset0.175983d (0.024687phase), full-SB1-covariance linear propagated Gaia uncertainty0.072295d at the measured epoch. Near-Gaia-reference projected eclipse offset0.058645d (photometric period projection allowance0.001043d). The approximate central duration5.36h vs observed median4.29h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated V eclipses show sector-dependent morphology and fitted depths; raw baseline/shape systematics remain and fitted depths are diluted. No detailed binary characterization claimed.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 167923097: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 5 distinct eclipse events in selected sectors[9, 62, 100]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=15.9435356330 Ã‚±0.0000166784d, reference eclipse epoch BTJD1560.4521364, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S35 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation9.287arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.537. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths226.324/220.069/212.394ppt, with 2 stacked events. QLP selected-kind fitted median241.112ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3546644935145490521 6, P=15.9431608845Ã‚±0.0084437670d, e=0.133116, omega=261.7914deg. Closest edge-on conjunction offset-0.439652d (-0.027576phase), full-SB1-covariance linear propagated Gaia uncertainty0.577385d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.467008d (photometric period projection allowance0.001218d). The approximate central

duration6.93h vs observed median5.11h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated V eclipses in sectors9/62/100; aperture differences and0.44pixel deficit offset retained; no capable listed neighbor.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 406297889: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 23 distinct eclipse events in selected sectors[14, 55, 82]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 23 same-kind midtimes give P=2.8227799299 Ã‚±0.0000039347d, reference eclipse epoch BTJD1685.8956770, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S55 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation2.266arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.408. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths87.296/81.926/78.810ppt, with 10 stacked events. QLP selected-kind fitted median95.040ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3186066906917655616O, P=2.8228180213Ã‚±0.0000945775d, e=0.034549, omega=126.9402deg. Closest edge-on conjunction offset-0.025598d (-0.009068phase), full-SB1-covariance linear propagated Gaia uncertainty0.046441d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.008114d (photometric period projection allowance0.001806d). The approximate central

duration4.60h vs observed median4.16h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated raw events across sectors14/55/82 with stable isolated morphology; no capable listed neighbor.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R364. TIC 160258534

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 160258534: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 7 distinct eclipse events in selected sectors[15, 56, 83]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=7.7049863920 Ã‚±0.0000097839d, reference eclipse epoch BTJD1730.5945848, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S55 deficit peak[8, 7] vs target pixel[7, 7]; deficit-target separation1.654arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.519. Capable neighbours: Gaia 1951244157007311360: 49.79 arcsec, G13.296, required fractional eclipse0.491; Gaia 1951244569324172288: 53.83 arcsec, G13.622, required fractional eclipse0.628
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths89.365/86.649/69.479ppt, with 3 stacked events. QLP selected-kind fitted median96.211ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3195124453496447872O, P=7.7037472107Ã‚±0.0008325053d, e=0.045926, omega=218.2302deg. Closest edge-on conjunction offset0.215587d (0.027985phase), full-SB1-covariance linear propagated Gaia uncertainty0.179708d at the measured epoch. Near-Gaia-reference projected eclipse offset-

0.000030d (photometric period projection allowance0.001702d). The approximate central duration4.74h vs observed median3.64h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated eclipses across sectors15/56/83; capable neighbors2.51/2.73pixels from deficit versus target0.079pixel. Pixel core supports target at TESS resolution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
15	2	1730.5844469	0.010417	99.373	used in ephemeris

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 16809274: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 8 distinct eclipse events in selected sectors[15, 82, 83]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=14.7258719722 Ã‚±0.0000898281d, reference eclipse epoch BTJD1714.5124553, kind: Shallower repeating eclipse, even historical half-period cycles; not asserted to be deeper primary. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S56 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.360arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.958. Capable neighbours: Gaia 1897254734463908352: 24.02 arcsec, G13.330, required fractional eclipse0.305
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths55.552/50.247/40.055ppt, with 4 stacked events. QLP selected-kind fitted median58.352ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3189725473016727052 8, P=14.7287368632Ã‚±0.0029848195d, e=0.026585, omega=301.3580deg. Closest edge-on conjunction offset-0.254052d (-0.017249phase), full-SB1-covariance linear propagated Gaia uncertainty0.301075d at the measured epoch. Near-Gaia-reference projected eclipse offset0.003788d (photometric period projection allowance0.008085d). The approximate central duration15.06h vs observed median14.83h permits noncentral geometry; this radius/minimum-

mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Persistent unequal alternating eclipses establish doubled orbital period relative to historical SAP half-period7.363d. Even historical cycles are the shallower event; only those five measured events define the ephemeris, explicitly not called deeper primary. Odd deeper events remain in raw evidence. Capable neighbor1.046pixels from deficit versus target0.160pixel; target core favors attribution. Historical cutout stack mixes eclipse kinds.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 279065540: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 9 distinct eclipse events in selected sectors[58, 85]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 9 same-kind midtimes give P=5.2403431586 Ã‚±0.0000058932d, reference eclipse epoch BTJD2883.0673999, kind: Selected repeating eclipse, primary by convention; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S58 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation5.250arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.844. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths213.830/201.663/167.136ppt, with 6 stacked events. QLP selected-kind fitted median216.202ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3430965367901091456, P=5.2403509794Ã‚±0.0002055046d, e=0.240755, omega=135.7897deg. Closest edge-on conjunction offset0.000412d (0.000079phase), full-SB1-covariance linear propagated Gaia uncertainty0.104181d at the measured epoch. Near-Gaia-reference projected eclipse offset0.004135d (photometric period projection allowance0.002805d). The approximate central duration5.07h vs

observed median3.31h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated isolated eclipses across sectors58/85; no capable listed neighbor. Aperture dilution retained.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 439808137: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 10 distinct eclipse events in selected sectors[42, 82, 92]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 10 same-kind midtimes give P=6.4350026636 ±0.0000108672d, reference eclipse epoch BTJD2448.1647207, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S82 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation3.089arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.286. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths102.553/100.621/93.986ppt, with 4 stacked predicted windows. QLP selected-kind fitted median105.158ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3267624023720201254 4, P=6.4354242696±0.0006605117d, e=0.023885, omega=293.9222deg. Closest edge-on conjunction offset-0.099754d (-0.015501phase), full-SB1-covariance linear propagated Gaia uncertainty0.226322d at the measured epoch. Near-Gaia-reference projected eclipse offset0.035159d (photometric period projection allowance0.003477d). The approximate central

duration5.54h vs observed median4.53h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Representative raw eclipses recur. Depths remain diluted and sector dependent; timing errors omit uncalibrated extraction and shape systematics.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: PLAUSIBLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Joint variability/eclipse model and radii check

Archived source: sanitized report text.

TIC 382631802: PLAUSIBLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: recurrence detected; eclipse interpretation insecure.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 28 distinct eclipse events in selected sectors[1, 36, 97]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 28 same-kind midtimes give P=2.5954869623 ±0.0000430249d, reference eclipse epoch BTJD1328.5030929, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Freshly extracted S97 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation4.628arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.460. Capable neighbours: Gaia 5290921322334100480: 48.54 arcsec, G16.282, required fractional eclipse0.564; Gaia 5290921287974360448: 57.75 arcsec, G16.856, required fractional eclipse0.951
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths5.739/5.663/5.407ppt, with 19 stacked predicted windows. QLP selected-kind fitted median8.947ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: unresolved after completed check.** DR35290921356693837568, P=2.5956559888±0.0001178502d, e=0.268983, omega=78.2783deg. Closest edge-on conjunction offset-0.055532d (-0.021394phase), full-SB1-covariance linear propagated Gaia uncertainty0.064915d at the measured epoch. Near-Gaia-reference projected eclipse

offset0.005655d (photometric period projection allowance0.015575d). The approximate central duration3.21h vs observed median7.58h exceeds the simple model and remains unresolved; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: PLAUSIBLE: recurring V-shaped dips ride structured variability. No stable sharp contacts or flat-bottomed occultation signature is resolved across representative windows; free trapezoids alone do not distinguish eclipses from pulsation or tidal minima. Eclipse interpretation itself is insecure. Free trapezoid duration median7.58h exceeds approximate central3.21h using TIC radius1.64solar and main-sequence minimum-mass companion. Difference centroid favors target0.220pixel versus capable neighbours2.38/2.67pixel; PSF fractional residual0.46 limits precision. Peak is measured within the central target5x5 box, excluding invalid peripheral cutout pixels; peripheral invalid pixels do not decide attribution. Model durations vary1.58-14.05h, indicating baseline/shape contamination. Timing reduced chi-square about126 requires scatter inflation. Geometry and eclipse identity are unresolved after completed checks; alternative variability and revised radii require testing.

Next check: Fit pulsation/background and eclipse jointly; test stellar radii and obtain resolved photometry.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

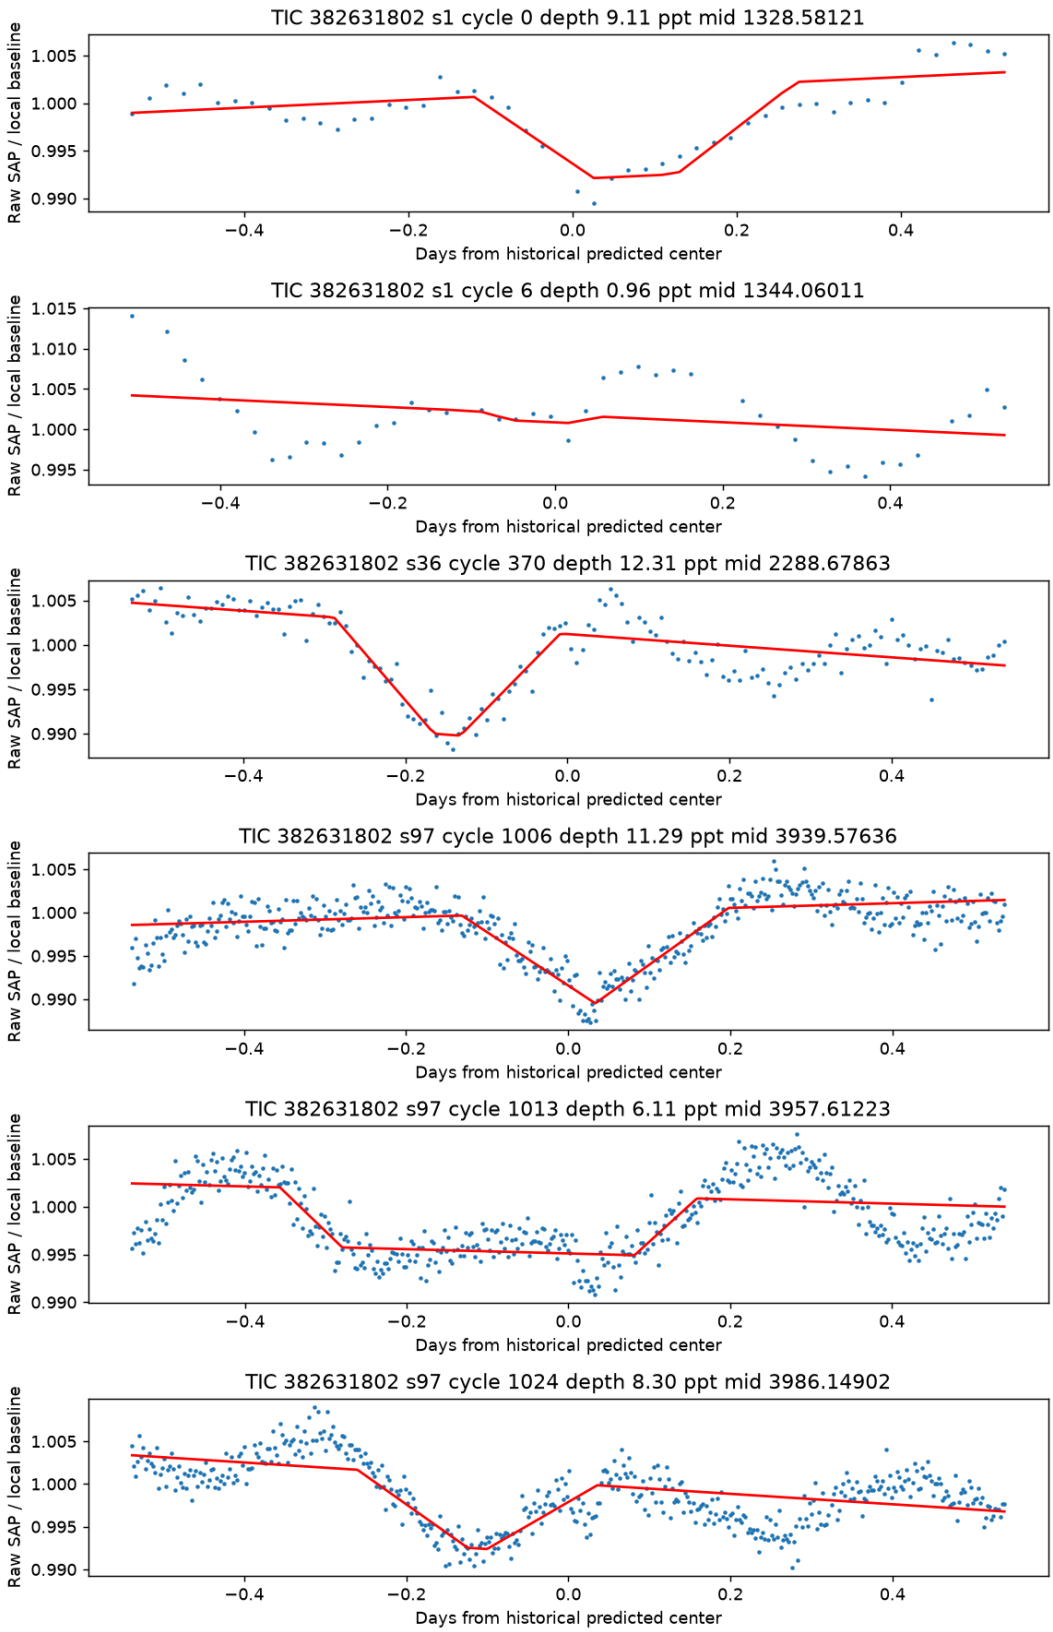
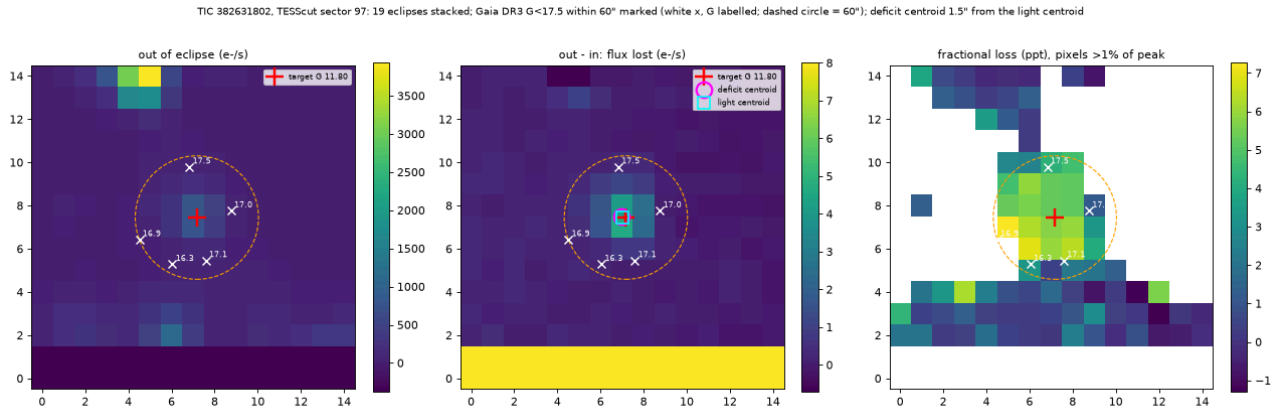
Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, shared-qlp QLP FITS; historical/diff_s97.json, historical/diff_s97.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are diffstack.py and c3_sapdepth.py in the source sb1-scale tree. No historical evidence overwritten.

Stable review key: R368. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.

Direct public evidence: measured events, raw eclipse plots, raw flux windows, Gaia geometry, independent audit, difference image.



R368; raw-events.png. Representative actual raw-flux eclipse windows. The full report retains timing, cadence-quality and alias qualifications.



R368; diff_s97.png. New sector-97 difference-image stack from 19 predicted-guided windows. The deficit favours the target, while structured variability and broad-model duration tension leave the eclipse interpretation insecure; this plausible signal is excluded.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 239572145: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 17 distinct eclipse events in selected sectors[15, 55, 82]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=6.3129271986 ±0.0000162239d, reference eclipse epoch BTJD1714.9544368, kind: Deeper eclipse; even historical half-period cycles. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S55 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation1.430arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.792. Capable neighbours: Gaia 1852594221418982144: 28.33 arcsec, G13.286, required fractional eclipse0.278
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths98.238/86.360/78.576ppt, with 8 stacked predicted windows. QLP selected-kind fitted median150.972ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3185259425577871948 8, P=6.3125426224±0.0003139626d, e=0.044112, omega=17.4791deg. Closest edge-on conjunction offset0.190656d (0.030203phase), full-SB1-covariance linear propagated Gaia uncertainty0.071723d at the measured epoch. Near-Gaia-reference projected eclipse offset0.109895d (photometric period projection allowance0.003407d). The approximate central duration6.77h vs observed median5.69h

permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Stable alternating depths near150/55ppt establish doubled orbital period; six deeper even historical half-period events define ephemeris. Historical pixel stack mixes both eclipse kinds; concentrated target deficit supports localization. Closest Gaia conjunction offset+0.1907d (0.0302phase) versus linear covariance0.0717d is retained as descriptive association tension without arbitrary sigma veto.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 90285860: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 3 distinct eclipse events in selected sectors[41, 74]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 3 same-kind midtimes give P=18.5945632879 ±0.0000559615d, reference eclipse epoch BTJD2422.5645534, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S41 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.713arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.356. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths162.253/156.481/137.458ppt, with 2 stacked predicted windows. QLP selected-kind fitted median178.980ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3202580461748610099 2, P=18.5977982181±0.0019708206d, e=0.436172, omega=250.9028deg. Closest edge-on conjunction offset-0.451898d (-0.024298phase), full-SB1-covariance linear propagated Gaia uncertainty0.202050d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.099291d (photometric period projection allowance0.006100d). The approximate central

duration10.47h vs observed median7.88h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Three measured eclipses include within-sector S41 recurrence, testing long-baseline cycle count. Closest Gaia conjunction offset-0.4519d (-0.0243phase) versus propagated0.2020d is retained as descriptive association tension, without arbitrary sigma veto; updated spectroscopy would test it.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 74717164: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 12 distinct eclipse events in selected sectors[8, 36, 89]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 12 same-kind midtimes give P=4.7665054846 ±0.0000054999d, reference eclipse epoch BTJD1520.9571959, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S62 deficit peak[7, 8] vs target pixel[7, 7]; deficit-target separation4.426arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.268. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths145.095/137.072/121.642ppt, with 6 stacked predicted windows. QLP selected-kind fitted median161.796ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3542726880006204979 2, P=4.7669038760±0.0002652066d, e=0.011747, omega=19.5123deg. Closest edge-on conjunction offset-0.096457d (-0.020235phase), full-SB1-covariance linear propagated Gaia uncertainty0.084036d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.002038d (photometric period projection allowance0.001303d). The approximate central

duration6.18h vs observed median5.64h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Representative raw eclipses recur. Depths remain diluted and sector dependent; timing errors omit uncalibrated extraction and shape systematics.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 134193638: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 15 distinct eclipse events in selected sectors[6, 34, 88]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 15 same-kind midtimes give P=4.0538858989 ±0.0000171546d, reference eclipse epoch BTJD1476.1660599, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S87 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.286arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.191. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths30.037/30.552/28.579ppt, with 5 stacked predicted windows. QLP selected-kind fitted median31.643ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3555934513038192742 4, P=4.0539744870±0.0004631847d, e=0.084801, omega=205.8049deg. Closest edge-on conjunction offset-0.087266d (-0.021526phase), full-SB1-covariance linear propagated Gaia uncertainty0.124551d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.063525d (photometric period projection allowance0.004597d). The approximate central

duration9.97h vs observed median5.67h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated sharp raw eclipses coexist with strong oscillatory variability, especially sectors34/88. Free trapezoids can absorb background oscillation; timing reduced chi-square about9 is scatter inflated and uncalibrated shape/baseline systematics remain.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 34588199: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX show 11 distinct eclipse events in selected sectors[6, 33, 87]. The raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=5.6182034108 ±0.0000064767d, reference eclipse epoch BTJD1470.7824555, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. Local recurrence where covered and alternating depths are recorded in alias-audit.json. No exhaustive blind search claimed. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S6 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation0.933arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.203. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths54.615/54.342/52.630ppt, with 4 stacked predicted windows. QLP selected-kind fitted median52.670ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3294492744700969356 8, P=5.6184294916±0.0004145044d, e=0.061222, omega=210.8797deg. Closest edge-on conjunction offset-0.086507d (-0.015397phase), full-SB1-covariance linear propagated Gaia uncertainty0.104403d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.042873d (photometric period projection allowance0.001250d). The approximate central

duration4.38h vs observed median4.07h permits noncentral geometry; this radius/minimum-mass estimate is not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Representative raw eclipses recur. Depths remain diluted and sector dependent; timing errors omit uncalibrated extraction and shape systematics.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 66787531: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 6 distinct eclipse events in selected sectors[76, 84]. The representative raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 6 same-kind midtimes give P=8.4698323955 +/-0.0000408947d, reference eclipse epoch BTJD3372.5340791, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S57 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation4.885arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.438. Capable neighbours: Gaia 1985288988373538176: 29.23 arcsec, G16.005, required fractional eclipse0.649; Gaia 1985288610416416640: 50.84 arcsec, G15.933, required fractional eclipse0.608; Gaia 1985291565353912576: 51.60 arcsec, G15.706, required fractional eclipse0.496
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths14.138/14.120/13.460ppt, with 3 stacked events. QLP selected-kind fitted median16.163ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR31985288988373538432, P=8.4702687962+/-0.0005995472d, e=0.283327, omega=345.7269deg. Closest edge-on conjunction offset-0.194463d (-0.022958phase), full-SB1-covariance linear propagated Gaia uncertainty0.221120d at the measured epoch. Near-Gaia-reference projected eclipse offset-

0.040850d (photometric period projection allowance0.014395d). The approximate central duration6.26h vs observed median2.26h is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated eclipses; deficit0.233pixel from target versus nearest capable neighbor1.675pixels. Aperture dilution limits intrinsic depth.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
76	192	3372.5337087	0.001432	16.326	used in ephemeris

Archived source: sanitized report text.

TIC 382603504: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 40 distinct eclipse events in selected sectors[30, 97]. The representative raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 17 same-kind midtimes give P=2.8391421780 +/-0.0000023540d, reference eclipse epoch BTJD2118.3611320, kind: Deeper eclipse; even historical half-period cycles. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S97 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.862arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.283. Capable neighbours: Gaia 4701453381830346240: 25.74 arcsec, G16.574, required fractional eclipse0.169; Gaia 4701453381830346368: 26.90 arcsec, G15.507, required fractional eclipse0.064; Gaia 4701453205735853312: 57.51 arcsec, G17.719, required fractional eclipse0.480
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths2.222/2.431/2.231ppt, with 36 stacked events. QLP selected-kind fitted median3.568ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR34701453381830347008, P=2.8391342975+/-0.0000612090d, e=0.037138, omega=190.6897deg. Closest edge-on conjunction offset-0.008284d (-0.002918phase), full-SB1-covariance linear propagated Gaia uncertainty0.045358d at the measured epoch. Near-Gaia-reference projected eclipse offset-

0.013083d (photometric period projection allowance0.001434d). The approximate central duration5.86h vs observed median1.48h is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Persistent unequal alternating eclipses: even historical half-period cycles are deeper; only those17 measured events define the orbital ephemeris. Half-period is rejected by unequal parity depths in both sectors. Target deficit0.089pixel versus capable neighbor1.360pixels.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Archived source: sanitized report text.

TIC 305651410: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 7 distinct eclipse events in selected sectors[15, 56, 83]. The representative raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=9.0437491336 +/-0.0000163681d, reference eclipse epoch BTJD1713.5371983, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S55 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation1.245arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.552. Capable neighbours: Gaia 1970480765776344576: 11.46 arcsec, G15.095, required fractional eclipse0.273; Gaia 1970480731416602240: 22.41 arcsec, G16.071, required fractional eclipse0.650; Gaia 1970480731416603904: 27.53 arcsec, G14.779, required fractional eclipse0.207; Gaia 1970480765776343040: 31.00 arcsec, G16.117, required fractional eclipse0.678; Gaia 1970480697056864384: 31.24 arcsec, G15.472, required fractional eclipse0.380; Gaia 1970480765776350464: 31.53 arcsec, G13.473, required fractional eclipse0.072; Gaia 1970480765776345088: 40.75 arcsec, G16.360, required fractional eclipse0.845; Gaia 1970480692753954688: 45.53 arcsec, G15.647, required fractional eclipse0.445; Gaia 1970480765776357760: 50.87 arcsec, G16.188, required fractional eclipse0.723; Gaia 1970480800136095616: 54.22 arcsec, G15.066, required fractional eclipse0.266; Gaia 1970480834495821184: 54.26 arcsec, G16.336, required fractional eclipse0.827; Gaia

1970480795828502144: 57.10 arcsec, G15.860, required fractional eclipse0.538; Gaia 1970492551166619008: 59.04 arcsec, G16.503, required fractional eclipse0.962

4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths12.607/11.644/9.927ppt, with 3 stacked events. QLP selected-kind fitted median13.481ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3197048073141660403 2, P=9.0416084657+/-0.0035950535d, e=0.190327, omega=178.9507deg. Closest edge-on conjunction offset-0.145031d (-0.016040phase), full-SB1-covariance linear propagated Gaia uncertainty0.461576d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.457568d (photometric period projection allowance0.002390d). The approximate central duration6.12h vs observed median4.52h is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated flat-bottom eclipses; crowded field includes capable neighbor0.550pixel from deficit versus target0.059pixel. Full difference core favors target but subpixel crowding limits precision.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 343340931: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 9 distinct eclipse events in selected sectors[12, 93, 103]. The representative raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 9 same-kind midtimes give P=6.1520562408 +/-0.0000181837d, reference eclipse epoch BTJD1630.7654348, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: unresolved after check.** Historical S13 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation3.996arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.153. Capable neighbours: Gaia 5801411754927216640: 2.88 arcsec, G14.241, required fractional eclipse0.205
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths21.316/20.867/20.807ppt, with 4 stacked events. QLP selected-kind fitted median20.390ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35801411754927217024, P=6.1527422755+/-0.0006366165d, e=0.140362, omega=312.4429deg. Closest edge-on conjunction offset-0.155060d (-0.025202phase), full-SB1-covariance linear propagated Gaia uncertainty0.137697d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.016481d (photometric period projection allowance0.003673d). The approximate central duration4.79h vs observed median9.82h is a radius/minimum-mass illustration, not a detailed

binary fit. TIC radius/mass are unavailable for this target; the solar fallback is not a physical duration constraint. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Attribution remains unresolved: capable neighbor only2.879arcsec from target, required intrinsic eclipse0.205; deficit distances0.190pixel to target and0.282pixel to neighbor are insufficient to distinguish these sources reliably. TIC mass/radius absent; approximate solar-fallback duration4.79h cannot constrain observed9.82h. Gaia association remains possible; source assignment needs resolved photometry.

Next check: Resolved eclipse photometry or multi-source PRF localization of this signal.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
12	0	1630.7613410	0.010417	20.390	used in ephemeris
12	1	1636.9100316	0.010417	19.672	used in ephemeris

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 421951253: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 11 distinct eclipse events in selected sectors[1, 68, 95]. The representative raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=5.1102857278 +/-0.0000053139d, reference eclipse epoch BTJD1327.5694426, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S28 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.504arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.101. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths43.861/43.412/43.001ppt, with 4 stacked events. QLP selected-kind fitted median42.001ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3681996379463091878 4, P=5.1105848877+/-0.0003627777d, e=0.081883, omega=85.1163deg. Closest edge-on conjunction offset-0.052807d (-0.010333phase), full-SB1-covariance linear propagated Gaia uncertainty0.073267d at the measured epoch. Near-Gaia-reference projected eclipse offset0.002239d (photometric period projection allowance0.000978d). The approximate central duration5.61h vs observed median4.43h is a radius/minimum-mass illustration, not a detailed

binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated isolated eclipses across widely separated sectors; no capable listed neighbor. Diluted fitted depths vary by sector aperture.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Archived source: sanitized report text.

TIC 128825695: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 21 distinct eclipse events in selected sectors[56, 83]. The representative raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 11 same-kind midtimes give P=4.8028045149 +/-0.0000048724d, reference eclipse epoch BTJD2826.0721681, kind: Deeper eclipse; even historical half-period cycles. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S56 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation1.753arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.408. Capable neighbours: Gaia 1904568750234102400: 51.23 arcsec, G12.586, required fractional eclipse0.043
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths13.142/12.399/10.344ppt, with 12 stacked events. QLP selected-kind fitted median17.106ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3190456871587436416O, P=4.8031801465+/-0.0002357494d, e=0.067203, omega=233.4166deg. Closest edge-on conjunction offset-0.165546d (-0.034466phase), full-SB1-covariance linear propagated Gaia uncertainty0.124919d at the measured epoch. Near-Gaia-reference projected eclipse offset0.024899d (photometric period projection allowance0.002470d). The approximate central duration6.52h vs observed median3.05h is a radius/minimum-mass illustration, not a detailed

binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating eclipses establish doubled orbital period relative to historical SAP half branch. Even11 deeper events define ephemeris; odd secondary timings excluded. Target deficit0.083pixel versus capable neighbor2.531pixels.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Archived source: sanitized report text.

TIC 9262715: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 7 distinct eclipse events in selected sectors[20, 47, 60]. The representative raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=7.3625774772 +/-0.0000348536d, reference eclipse epoch BTJD1846.2999364, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S47 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.380arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.643. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths100.072/97.050/85.495ppt, with 4 stacked events. QLP selected-kind fitted median109.006ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3923996517914746624, P=7.3632161676+/-0.0009799956d, e=0.069654, omega=157.7983deg. Closest edge-on conjunction offset-0.175911d (-0.023890phase), full-SB1-covariance linear propagated Gaia uncertainty0.198272d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.049450d (photometric period projection allowance0.006901d). The approximate central duration5.42h vs observed median3.68h is a radius/minimum-mass illustration, not a detailed

binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Seven deep repeated eclipses across sectors20/47/60, including sector47 consecutive cycles100-103. No capable listed neighbor.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 394620087: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 5 distinct eclipse events in selected sectors[54, 81]. The representative raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=6.8947331077 +/-0.0000236096d, reference eclipse epoch BTJD2771.8036128, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S40 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.578arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.547. Capable neighbours: Gaia 2045989451938846336: 30.87 arcsec, G13.589, required fractional eclipse0.594
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths101.759/96.507/82.787ppt, with 2 stacked events. QLP selected-kind fitted median104.974ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR32045989413267218816, P=6.8950679495+/-0.0005730378d, e=0.015067, omega=339.7470deg. Closest edge-on conjunction offset-0.094934d (-0.013768phase), full-SB1-covariance linear propagated Gaia uncertainty0.216787d at the measured epoch. Near-Gaia-reference projected eclipse offset0.020921d (photometric period projection allowance0.008169d). The approximate central duration7.07h vs observed median5.28h is a radius/minimum-mass illustration, not a detailed

binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Five deep repeated eclipses across sectors54/81, including consecutive cycles266/267. Target deficit0.123pixel versus capable neighbor1.436pixels.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 443900773: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 8 distinct eclipse events in selected sectors[7, 46, 88]. The representative raw-event plot and numeric raw-windows.csv were inspected. Broadly repeated morphology is retained even when individual shallow fits are noisy. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=9.3257982069 +/-0.0000153302d, reference eclipse epoch BTJD1496.6547499, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S7 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.805arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.082. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths351.148/350.810/345.926ppt, with 3 stacked events. QLP selected-kind fitted median379.302ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3649664385352561664, P=9.3257311444+/-0.0008100741d, e=0.014226, omega=280.9488deg. Closest edge-on conjunction offset0.022938d (0.002460phase), full-SB1-covariance linear propagated Gaia uncertainty0.121549d at the measured epoch. Near-Gaia-reference projected eclipse offset0.014958d (photometric period projection allowance0.001824d). The approximate central duration5.30h vs observed median4.31h

is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep repeated flat-bottom eclipses across sectors7/46/88; no capable listed neighbor. Fitted depths differ by aperture and sector; no detailed binary characterization.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R387. TIC 438188407

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization

Archived source: sanitized report text.

TIC 438188407: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 5 fitted event windows in sectors [6, 45, 87] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 5 same-kind measured centers give P = 12.9836788156 +/- 0.0000267918 d and reference epoch BTJD 1479.9810460. Epoch kind: Selected repeating eclipse; deeper/secondary identity not independently established. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: pass at TESS resolution.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 33 deficit-target distance 0.173 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: Gaia 3331368224678745984: separation 49.058 arcsec, required intrinsic fractional eclipse 0.6145, deficit distance 2.329 pixel; Gaia 3331368057179759104: separation 49.704 arcsec, required intrinsic fractional eclipse 0.4503, deficit distance 2.248 pixel Required intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 227.353/172.916/101.983 ppt from 2 stacked events; current selected-kind QLP median 243.437 ppt. These are reductions of the same TESS photons, not independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.
5. **Gaia orbital geometry: pass with limitations.** DR3 3331368263337545984, P = 12.9857302396 +/- 0.0030179827 d, e = 0.079374, omega = 18.5457 deg. Closest edge-on conjunction is offset -0.270572 d (-0.020836 phase), with full SB1 covariance linear propagated

uncertainty 0.318309 d at measured epoch. Projection near Gaia reference gives offset -0.098252 d; photometric period projection allowance 0.002251 d excludes covariance and model systematics. Approximate central duration 11.75 h versus fitted median 10.12 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Deep repeated flat-bottom eclipses in three widely separated sectors. Capable neighbors are more than 2.24 pixels from the deficit, versus target 0.173 pixel. Gaia period drift is acknowledged through propagated covariance; no arbitrary formal-error veto is used.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing input error d	Depth ppt	Timing status
6	0	1479.9813931	0.0104167	228.946	used
45	81	2531.6591248	0.0034724	249.018	used
45	82	2544.6425545	0.0034724	247.986	used

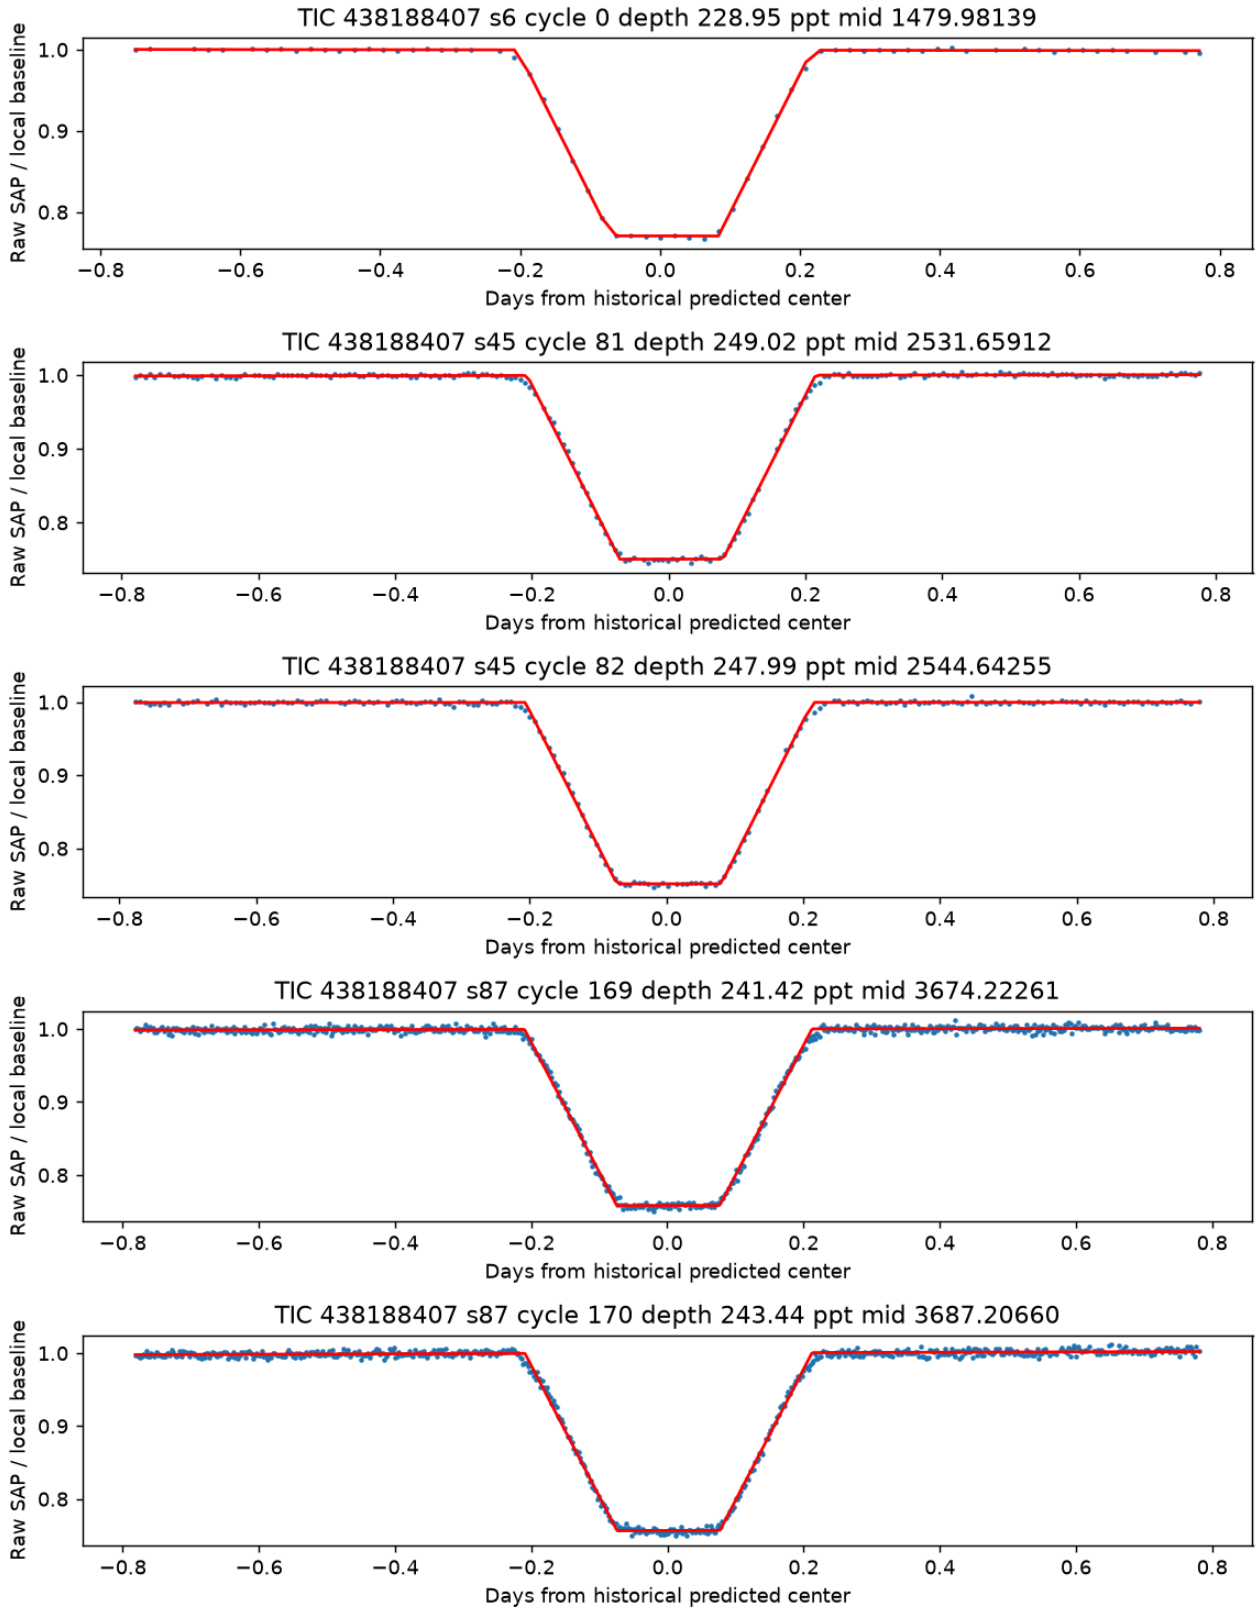
87	170	3687.2066030	0.0011574	243.437	used

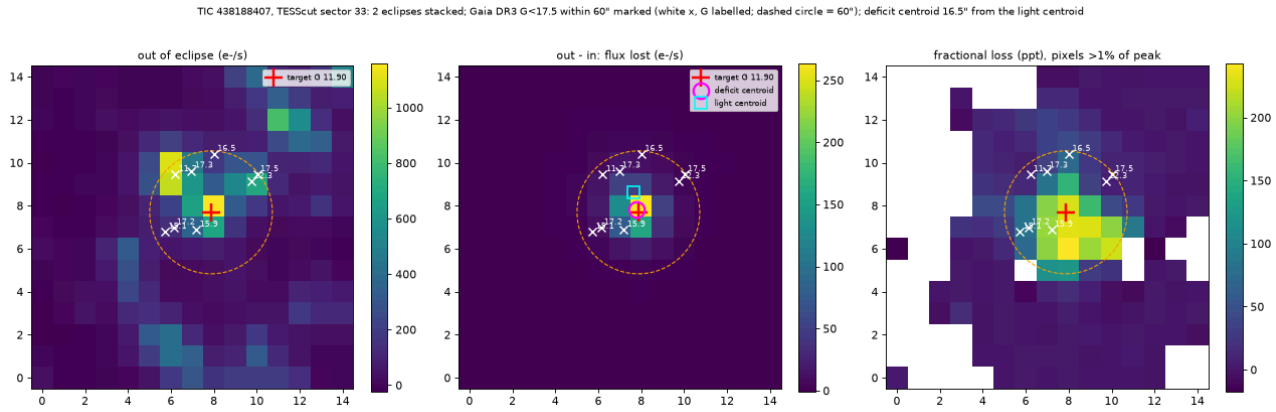
Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, historical/diff_s33.json, historical/diff_s33.png, historical/gaia.json; batch ../pixel-audit.json, ../alias-audit.json, ../gaia-geometry.json, ../helper-audit.md and ../SHA256SUMS.json. Raw cutout: [local path omitted] Historical extraction definitions: [local path omitted] and c3_sapdepth.py. Reused source hashes in source-hashes.json; no historical evidence overwritten.

Stable review key: R387. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.

Direct public evidence: measured events, raw eclipse plots, raw flux windows, Gaia geometry, independent audit, difference image.



R387; raw-events.png. Representative actual raw-flux eclipse windows. The full report retains timing, cadence-quality and alias qualifications.



R387; diff_s33.png. Target-pixel eclipse-deficit evidence. The full report retains capable-neighbour and angular-resolution qualifications.

R388. TIC 62337815

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization

Archived source: sanitized report text.

TIC 62337815: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 4 fitted event windows in sectors [76, 83] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 4 same-kind measured centers give P = 11.5008928530 +/- 0.0000784016 d and reference epoch BTJD 3378.3037354. Epoch kind: Selected repeating eclipse; deeper/secondary identity not independently established. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: pass at TESS resolution.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 55 deficit-target distance 0.249 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: Gaia 2166153703341315968: separation 12.253 arcsec, required intrinsic fractional eclipse 0.2344, deficit distance 0.833 pixel Required intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 16.077/16.162/15.507 ppt from 2 stacked events; current selected-kind QLP median 20.247 ppt. These are reductions of the same TESS photons, not independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.
5. **Gaia orbital geometry: pass with limitations.** DR3 2166153699041263360, P = 11.5003902549 +/- 0.0013799967 d, e = 0.048491, omega = 318.6830 deg. Closest edge-on conjunction is offset 0.067766 d (0.005892 phase), with full SB1 covariance linear propagated uncertainty 0.357581 d at measured epoch. Projection near Gaia reference gives offset -0.062910 d;

photometric period projection allowance 0.020384 d excludes covariance and model systematics. Approximate central duration 7.79 h versus fitted median 3.44 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Four isolated flat-bottom eclipses in sectors 76/83 with consecutive cycles in each. The 12.25 arcsec capable neighbor is 0.833 pixel from the deficit versus target 0.249 pixel; full image favors target, with residual subpixel crowding limitation.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing input error d	Depth ppt	Timing status

R389. TIC 399285183

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization

Archived source: sanitized report text.

TIC 399285183: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 7 fitted event windows in sectors [54, 81] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 7 same-kind measured centers give P = 3.8060033593 +/- 0.0000370371 d and reference epoch BTJD 2771.5481179. Epoch kind: Selected repeating eclipse; deeper/secondary identity not independently established. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: pass at TESS resolution.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 81 deficit-target distance 0.142 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: Gaia 4242940643455267968: separation 26.034 arcsec, required intrinsic fractional eclipse 0.3477, deficit distance 1.135 pixel; Gaia 4242937654158029312: separation 38.743 arcsec, required intrinsic fractional eclipse 0.2899, deficit distance 1.942 pixel Required intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 12.498/11.543/10.458 ppt from 6 stacked events; current selected-kind QLP median 13.833 ppt. These are reductions of the same TESS photons, not independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.
5. **Gaia orbital geometry: pass with limitations.** DR3 4242940643455270144, P = 3.8059045398 +/- 0.0002783071 d, e = 0.147943, omega = 124.5770 deg. Closest edge-on conjunction is offset 0.034084 d (0.008956 phase), with full SB1 covariance linear propagated

uncertainty 0.161791 d at measured epoch. Projection near Gaia reference gives offset -0.027777 d; photometric period projection allowance 0.023185 d excludes covariance and model systematics. Approximate central duration 5.16 h versus fitted median 3.05 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Seven repeated localized shallow eclipses, with clean flat surrounding baseline in sector 81 and consecutive measured cycles. Capable neighbors are at least 1.135 pixels from the deficit versus target 0.142 pixel.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization

Archived source: sanitized report text.

TIC 399868192: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 7 fitted event windows in sectors [5, 71, 98] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 6 same-kind measured centers give P = 6.4834644669 +/- 0.0000125529 d and reference epoch BTJD 1457.0655796. Epoch kind: Selected repeating eclipse; deeper/secondary identity not independently established. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: pass at TESS resolution.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 98 deficit-target distance 0.057 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: Gaia 3291551648758099840: separation 37.753 arcsec, required intrinsic fractional eclipse 0.1130, deficit distance 1.860 pixel; Gaia 3291551614399361152: separation 42.464 arcsec, required intrinsic fractional eclipse 0.0417, deficit distance 2.031 pixel Required intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 29.732/24.057/11.964 ppt from 6 stacked events; current selected-kind QLP median 29.230 ppt. These are reductions of the same TESS photons, not independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.
5. **Gaia orbital geometry: pass with limitations.** DR3 3291551648758101248, P = 6.4836906195 +/- 0.0007693937 d, e = 0.248840, omega = 343.5160 deg. Closest edge-on conjunction is offset 0.204507 d (0.031542 phase), with full SB1 covariance linear propagated uncertainty 0.176224 d at

measured epoch. Projection near Gaia reference gives offset 0.241823 d; photometric period projection allowance 0.002071 d excludes covariance and model systematics. Approximate central duration 5.40 h versus fitted median 4.88 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Repeated flat-bottom eclipses across sectors 5/71/98. Sector 98 cycle 398 lacks ingress and has singular center covariance, so it is excluded from timing. Other consecutive events anchor the recurrence. Capable neighbors are at least 1.86 pixels from deficit versus target 0.057 pixel.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization

Archived source: sanitized report text.

TIC 457003443: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 13 fitted event windows in sectors [43, 45, 72] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 13 same-kind measured centers give P = 4.6443443385 +/- 0.0000089036 d and reference epoch BTJD 2479.0598944. Epoch kind: Selected repeating eclipse; deeper/secondary identity not independently established. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: pass at TESS resolution.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 43 deficit-target distance 0.218 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: Gaia 3379491619541073280: separation 29.470 arcsec, required intrinsic fractional eclipse 0.2631, deficit distance 1.708 pixel; Gaia 3379493092713030656: separation 43.785 arcsec, required intrinsic fractional eclipse 0.1467, deficit distance 2.360 pixel; Gaia 3379491580884499072: separation 45.533 arcsec, required intrinsic fractional eclipse 0.3374, deficit distance 2.052 pixel; Gaia 3379491516461860608: separation 49.600 arcsec, required intrinsic fractional eclipse 0.2856, deficit distance 2.277 pixel; Gaia 3379493028290345728: separation 51.857 arcsec, required intrinsic fractional eclipse 0.0408, deficit distance 2.845 pixel Required intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 8.270/8.372/7.000 ppt from 6 stacked events; current selected-kind QLP median 9.585 ppt. These are reductions of the same TESS photons, not

independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.

5. **Gaia orbital geometry: pass with limitations.** DR3 3379491615243515392, P = 4.6449635222 +/- 0.0019033067 d, e = 0.097546, omega = 281.9464 deg. Closest edge-on conjunction is offset -0.132312 d (-0.028485 phase), with full SB1 covariance linear propagated uncertainty 0.925255 d at measured epoch. Projection near Gaia reference gives offset 0.146321 d; photometric period projection allowance 0.004007 d excludes covariance and model systematics. Approximate central duration 7.92 h versus fitted median 4.14 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Repeated isolated flat-bottom shallow eclipses across sectors 43/45/72. Full deficit image favors target at 0.218 pixel; capable neighbors are at least 1.708 pixels away. Aperture dilution and baseline variability limit depth interpretation.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization

Archived source: sanitized report text.

TIC 76020303: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 35 fitted event windows in sectors [43, 45, 72] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 17 same-kind measured centers give P = 3.7052792516 +/- 0.0000054871 d and reference epoch BTJD 2475.6703770. Epoch kind: Even historical half-period cycles; indistinguishable-depth primary/secondary identity ambiguous. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: pass at TESS resolution.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 43 deficit-target distance 0.057 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: Gaia 3428849314988561024: separation 43.711 arcsec, required intrinsic fractional eclipse 0.9305, deficit distance 2.120 pixel; Gaia 3428849040110655872: separation 50.558 arcsec, required intrinsic fractional eclipse 0.4995, deficit distance 2.414 pixel; Gaia 3428849074470410880: separation 52.996 arcsec, required intrinsic fractional eclipse 0.3558, deficit distance 2.448 pixel Required intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 63.661/57.191/40.992 ppt from 12 stacked events; current selected-kind QLP median 68.620 ppt. These are reductions of the same TESS photons, not independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.
5. **Gaia orbital geometry: pass with limitations.** DR3 3428849104531235072, P = 3.7053469413 +/- 0.0001501581 d, e = 0.070651, omega = 327.6200 deg. Closest edge-on conjunction is offset

-0.106060 d (-0.028623 phase), with full SB1 covariance linear propagated uncertainty 0.092846 d at measured epoch. Projection near Gaia reference gives offset -0.067950 d; photometric period projection allowance 0.003089 d excludes covariance and model systematics. Approximate central duration 6.80 h versus fitted median 4.33 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Near-equal alternating eclipses recur every 1.85264 d. Same-parity even events give the reported orbital period 3.705279 d, consistent with Gaia 3.705347 d. Photometry alone retains the half-period interpretation because parity depths are indistinguishable; Gaia supplies the orbital interpretation, not an unannounced alias replacement. Both conjunctions are plausible for the paired eclipses. The target is 0.057 pixel from deficit versus capable neighbors beyond 2.12 pixels.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization

Archived source: sanitized report text.

TIC 251798466: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 4 fitted event windows in sectors [54, 81] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 3 same-kind measured centers give P = 9.0605146129 +/- 0.0008183987 d and reference epoch BTJD 3508.7680130. Epoch kind: Selected repeating eclipse; deeper/secondary identity not independently established. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: pass at TESS resolution.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 81 deficit-target distance 0.063 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: Gaia 4234971348825403520: separation 57.192 arcsec, required intrinsic fractional eclipse 0.4300, deficit distance 2.789 pixel Required intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 175.432/175.338/146.016 ppt from 2 stacked events; current selected-kind QLP median 197.169 ppt. These are reductions of the same TESS photons, not independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.
5. **Gaia orbital geometry: pass with limitations.** DR3 4234971451904627968, P = 9.0594815327 +/- 0.0012896050 d, e = 0.080359, omega = 152.2532 deg. Closest edge-on conjunction is offset 0.360772 d (0.039823 phase), with full SB1 covariance linear propagated uncertainty 0.487312 d at measured epoch. Projection near Gaia reference gives offset 0.005392 d; photometric period

projection allowance 0.281529 d excludes covariance and model systematics. Approximate central duration 7.29 h versus fitted median 5.13 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Three complete deep eclipses in sector 81, consecutive cycles 81-83, measure the period. Earlier sector 54 cycle 0 is a visibly partial raw repeat and supports recurrence but contributes no precision timing. Only the short complete-event baseline sets the stated formal error. Target deficit 0.063 pixel versus capable neighbor 2.789 pixels.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing input error d	Depth ppt	Timing status
54	0	2774.8017000	0.0069444	103.705	Partially covered eclipse lacks ingress baseline; retained raw morphology but excluded timing.

physical_verdict: PROBABLE

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Resolved eclipse photometry or calibrated multi-source PRF localization

Archived source: sanitized report text.

TIC 363264601: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 9 fitted event windows in sectors [100, 103] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 9 same-kind measured centers give P = 4.6066819596 +/- 0.0002625463 d and reference epoch BTJD 4076.6896945. Epoch kind: Selected repeating eclipse; deeper/secondary identity not independently established. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: unresolved after completed check.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 66 deficit-target distance 0.093 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: Gaia 5808791951859897216: separation 5.595 arcsec, required intrinsic fractional eclipse 0.0185, deficit distance 0.350 pixel; Gaia 5808792054939115264: separation 21.193 arcsec, required intrinsic fractional eclipse 0.4070, deficit distance 0.918 pixel; Gaia 5808791638319283328: separation 36.431 arcsec, required intrinsic fractional eclipse 0.8786, deficit distance 1.817 pixel; Gaia 5808791986219638784: separation 36.982 arcsec, required intrinsic fractional eclipse 0.6397, deficit distance 1.699 pixel; Gaia 5808792054939117184: separation 41.095 arcsec, required intrinsic fractional eclipse 0.0749, deficit distance 1.871 pixel; Gaia 5808792054939117568: separation 42.632 arcsec, required intrinsic fractional eclipse 0.6112, deficit distance 1.937 pixel; Gaia 5808791986219637120: separation 43.123 arcsec, required intrinsic fractional eclipse 0.0652, deficit distance 2.033 pixel; Gaia 5808791986219640960: separation 45.848 arcsec, required intrinsic fractional eclipse 0.1185, deficit distance 2.092 pixel; Gaia 5808792020579377024: separation 48.371 arcsec, required intrinsic fractional eclipse 0.0762, deficit distance 2.293 pixel; Gaia 5808791986219634432: separation 51.140 arcsec, required intrinsic fractional eclipse 0.5430, deficit distance 2.455 pixel Required

intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.

4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 3.366/3.092/3.043 ppt from 6 stacked events; current selected-kind QLP median 4.209 ppt. These are reductions of the same TESS photons, not independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.
5. **Gaia orbital geometry: pass with limitations.** DR3 5808791947555627648, P = 4.6068777227 +/- 0.0001919322 d, e = 0.090713, omega = 286.1038 deg. Closest edge-on conjunction is offset -0.248803 d (-0.054007 phase), with full SB1 covariance linear propagated uncertainty 0.160371 d at measured epoch. Projection near Gaia reference gives offset -0.091997 d; photometric period projection allowance 0.210300 d excludes covariance and model systematics. Approximate central duration 5.28 h versus fitted median 2.12 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Repeated localized 4-5 ppt depressions have flat surrounding baseline in sectors 100/103 and support genuine eclipses. Attribution remains unresolved after a completed check: a 5.595 arcsec neighbor can supply the signal with 1.85 percent intrinsic loss. Target/neighbor deficit distances 0.093/0.350 pixel favor the target but do not reliably distinguish these close sources without a calibrated localization. This is PROBABLE because the eclipses repeat and attribution is unresolved, not because their morphology is uncertain.

Next check: Resolved eclipse photometry or calibrated multi-source PRF localization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

R395. TIC 399089869

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization

Archived source: sanitized report text.

TIC 399089869: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 5 fitted event windows in sectors [23, 46, 91] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 5 same-kind measured centers give P = 8.8537610758 +/- 0.0000176369 d and reference epoch BTJD 1937.8424876. Epoch kind: Selected repeating eclipse; deeper/secondary identity not independently established. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: pass at TESS resolution.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 46 deficit-target distance 0.221 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: No capable listed source within the saved 60 arcsec cone. Required intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 106.328/108.693/103.991 ppt from 2 stacked events; current selected-kind QLP median 119.002 ppt. These are reductions of the same TESS photons, not independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.
5. **Gaia orbital geometry: pass with limitations.** DR3 3902848326747296000, P = 8.8536629216 +/- 0.0012623065 d, e = 0.154456, omega = 84.8249 deg. Closest edge-on conjunction is offset 0.064106 d (0.007241 phase), with full SB1 covariance linear propagated uncertainty 0.229109 d at measured epoch. Projection near Gaia reference gives offset 0.046929 d; photometric period projection allowance 0.003086 d excludes covariance and model systematics.

Approximate central duration 5.54 h versus fitted median 3.68 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Deep repeated isolated eclipses across sectors 23/46/91; sector 46 consecutive cycles 70/71 test recurrence. No capable neighbor in the saved 60 arcsec cone. Aperture-dependent dilution limits intrinsic depth.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

R396. TIC 329559935

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional resolved photometry or spectroscopy for precision characterization

Archived source: sanitized report text.

TIC 329559935: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. Current section 2.7 five-check standard applied; historical screening is not itself admission evidence.

1. **Raw flux: pass.** 12 fitted event windows in sectors [80] were examined in raw-events.png and numeric raw-windows.csv. Repeated localized ingress/egress depressions and surrounding baseline were visually inspected; trapezoid fits alone are not the eclipse interpretation. QLP raw SAP_FLUX with quality zero is used for these measurements. Coverage requirements are in review_measure.py; uncovered/flagged windows are not clean nulls. At most three spread available sectors were initially selected; no mandatory all-event or all-sector analysis is implied.
2. **Measured timing: pass.** 5 same-kind measured centers give P = 2.6037352194 +/- 0.0001586838 d and reference epoch BTJD 3480.4072501. Epoch kind: Odd historical half-period cycles; deeper eclipses. Predicted historical centers only seed windows and cycle counts, not measured timings. Within-sector recurrence/parity tests are retained in alias-audit.json; this is not an exhaustive blind alias scan. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated. Partial/singular fits remain documented and excluded; the epoch may denote a selected repeating eclipse rather than an independently established deeper primary.
3. **Source attribution: pass at TESS resolution.** Original cutout WCS/Gaia identity audited in pixel-audit.json. Saved sector 80 deficit-target distance 0.081 pixel; full deficit image examined against every flux-capable listed source. Capable neighbors: Gaia 4253888274641830912: separation 26.962 arcsec, required intrinsic fractional eclipse 0.1384, deficit distance 1.362 pixel; Gaia 4253888996196371968: separation 47.822 arcsec, required intrinsic fractional eclipse 0.9953, deficit distance 2.243 pixel; Gaia 4253888240282092416: separation 51.643 arcsec, required intrinsic fractional eclipse 0.7951, deficit distance 2.503 pixel; Gaia 4253888377721051648: separation 57.036 arcsec, required intrinsic fractional eclipse 0.5436, deficit distance 2.733 pixel; Gaia 4253888201559031424: separation 57.314 arcsec, required intrinsic fractional eclipse 0.5383, deficit distance 2.821 pixel; Gaia 4253888240282111232: separation 59.694 arcsec, required intrinsic fractional eclipse 0.4583, deficit distance 2.845 pixel Required intrinsic fractional eclipse and observed blended pixel fractional loss have different dilution and are not directly compared to exclude neighbors. The approximate G-band budget and saved 60 arcsec cone limit this check.
4. **Alternative reduction: pass.** Separately extracted background-subtracted target-centered TESScut 1x1/3x3/5x5 apertures show depths 54.387/43.686/32.724 ppt from 11 stacked events; current selected-kind QLP median 87.969 ppt. These are reductions of the same TESS photons, not

independent observing occasions. Dilution, aperture differences and mixed primary/secondary stacks can change depth; no claim of equal intrinsic depths is made.

5. **Gaia orbital geometry: pass with limitations.** DR3 4253888270275983360, P = 2.6038620064 +/- 0.0002119814 d, e = 0.081014, omega = 116.3438 deg. Closest edge-on conjunction is offset -0.048017 d (-0.018441 phase), with full SB1 covariance linear propagated uncertainty 0.202816 d at measured epoch. Projection near Gaia reference gives offset 0.102480 d; photometric period projection allowance 0.188358 d excludes covariance and model systematics. Approximate central duration 5.84 h versus fitted median 3.70 h is an illustration using TIC radius/mass and a minimum-mass main-sequence companion, not a fitted geometry. No arbitrary sigma veto; gaia-geometry.json preserves all assumptions and both conjunctions.

Deciding interpretation and limitations: Only sector 80 supplied usable selected QLP data. Unequal alternating depths (odd median about 87.97 ppt; even about 41.28 ppt) establish the doubled orbital period, with five measured odd deeper eclipses spanning cycles -1 to 15. Half-period recurrence mixes two unequal eclipse types. Measured 2.603735 d agrees with Gaia 2.603862 d within the descriptive timing uncertainty; queue 2.60568 d is a historical search value, not adopted. Target deficit 0.081 pixel versus capable neighbors beyond 1.362 pixels.

Next check: Optional resolved photometry or spectroscopy for precision characterization.

Catalogue novelty: see central ../../catalogues/coverage-matrix.csv; this report does not establish exhaustive literature priority. Current observed repeats remove a single-cycle availability question; the short-baseline cases explicitly state their evidence.

TIC 119193784: PROBABLE

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 4 distinct eclipse events in selected sectors[50, 91]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: conditional orbital alias.** 4 same-kind midtimes give P=10.4453149260 +/-0.0000244041d, reference eclipse epoch BTJD2669.7487457, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S50 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation4.008arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.570. Capable neighbours: Gaia 3645530720010524672: 41.07 arcsec, G12.275, required fractional eclipse0.268
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths112.056/101.074/78.404ppt, with 2 stacked events. QLP selected-kind fitted median122.868ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3364553078873000128O, P=10.4445071004+/-0.0023469310d, e=0.204078, omega=254.9518deg. Closest edge-on conjunction offset0.062988d (0.006031phase), full-SB1-covariance linear propagated Gaia uncertainty0.556629d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.113118d (photometric period projection allowance0.005320d). The approximate central

duration6.07h vs observed median4.30h is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four deep V-shaped/truncated-bottom events across S50/91, all odd historical10.445d cycles. Intermediate cycles0 and106 have zero quality-zero points within0.2d (42 and173 flagged points respectively), so neither is a clean null. Available QLP inventory lists only S50/91. Two20.8906d-separated pairs establish real repetition, but10.4453149d period is conditional on the Gaia-informed cycle count;20.8906d and integer-count aliases are not independently rejected. This missing orbital-alias check retains PROBABLE despite completed bounded inspection. Target deficit0.191pixel versus capable neighbor2.279pixels; dilution limits intrinsic depth.

Next check: Obtain clean intermediate-cycle photometry to distinguish10.445d from20.8906d orbital aliases.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
50	-1	2669.7487060	0.003472	125.471	used in conditional ephemeris
50	1	2690.6394133	0.003472	125.744	used in conditional ephemeris
91	105	3776.9521434	0.001157	120.265	used in conditional ephemeris
91	107	3797.8427424	0.001157	119.358	used in conditional ephemeris

Archived source: sanitized report text.

TIC 300148401: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 8 distinct eclipse events in selected sectors[6, 33, 98]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=8.7876379642 +/-0.0000126985d, reference eclipse epoch BTJD1469.3015561, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S32 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation1.674arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.504. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths45.737/46.373/45.311ppt, with 3 stacked events. QLP selected-kind fitted median52.895ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR32884583087778756224, P=8.7880603922+/-0.0014557943d, e=0.142219, omega=170.3694deg. Closest edge-on conjunction offset0.026216d (0.002983phase), full-SB1-covariance linear propagated Gaia uncertainty0.174132d at the measured epoch. Near-Gaia-reference projected eclipse offset0.078174d (photometric period projection allowance0.001562d). The approximate central duration6.82h vs observed median5.07h

is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated narrow eclipse cores on curved variable baseline; early S6 is sparse at30min cadence, while S33/98 resolve recurrence. Linear baseline and depth precision are limited by curvature; no capable listed neighbor.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 167125054: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 8 distinct eclipse events in selected sectors[1, 36, 98]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 8 same-kind midtimes give P=9.1223775152 +/-0.0000113717d, reference eclipse epoch BTJD1326.8709038, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S1 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation5.019arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.417. Capable neighbours: Gaia 5283286313593528192: 38.02 arcsec, G12.828, required fractional eclipse0.203
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths62.675/55.530/44.226ppt, with 3 stacked events. QLP selected-kind fitted median60.330ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3528328610313326220 8, P=9.1224018521+/-0.0010396464d, e=0.006947, omega=77.3211deg. Closest edge-on conjunction offset-0.079784d (-0.008746phase), full-SB1-covariance linear propagated Gaia uncertainty0.167676d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.077277d (photometric period projection allowance0.001171d). The approximate central duration10.42h vs observed median9.16h is a radius/minimum-mass illustration, not a detailed

binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated broad flat-bottom eclipses in S1/36/99; depth near60ppt. Target deficit0.239pixel versus capable neighbor2.036pixels.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R400. TIC 60514418

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 60514418: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 5 distinct eclipse events in selected sectors[43, 44, 71]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=11.6952161043 +/-0.0000339692d, reference eclipse epoch BTJD2475.7039155, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S44 deficit peak[8, 8] vs target pixel[8, 8]; deficit-target separation0.747arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.202. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths35.497/34.959/34.188ppt, with 2 stacked events. QLP selected-kind fitted median38.420ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3153384449055145856, P=11.6940432568+/-0.0012138569d, e=0.063286, omega=211.5158deg. Closest edge-on conjunction offset0.160480d (0.013723phase), full-SB1-covariance linear propagated Gaia uncertainty0.190129d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.048287d (photometric period projection allowance0.006047d). The approximate central duration8.77h vs observed median3.72h is a radius/minimum-mass illustration, not a detailed

binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated V-shaped eclipses in S43/44/71; consecutive S44 cycles test recurrence. No capable listed neighbor; observed duration3.72h is shorter than illustrative central duration8.77h, compatible with noncentral eclipse.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R401. TIC 257047728

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 257047728: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 2 distinct eclipse events in selected sectors[48]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 2 same-kind midtimes give P=15.2070674831 +/-0.0049104284d, reference eclipse epoch BTJD2612.2132742, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S40 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation0.295arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.154. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths21.672/22.494/22.800ppt, with 2 stacked events. QLP selected-kind fitted median24.411ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3170097228519837644 8, P=15.2066086810+/-0.0035990214d, e=0.279558, omega=176.3644deg. Closest edge-on conjunction offset0.002539d (0.000167phase), full-SB1-covariance linear propagated Gaia uncertainty0.530874d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.064446d (photometric period projection allowance0.716923d). The approximate central duration7.47h vs observed median3.46h is a radius/minimum-mass illustration, not a detailed

binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Two fully covered S48 eclipses are consecutive at15.20707d, directly testing recurrence rather than long-baseline integer counting. Historical S40 two-event difference stack supplies separate raw-pixel morphology; no capable listed neighbor. Timing precision is single-sector and not calibrated total uncertainty.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status
48	61	2612.2132742	0.003472	23.816	used in ephemeris
48	62	2627.4203417	0.003472	25.005	used in ephemeris

Evidence (original source layout; use the public evidence links below for exported locations): measurements.json, raw-events.png, raw-windows.csv, shared-qlp QLP FITS; historical/diff_s40.json, historical/diff_s40.png and historical/gaia.json; ../gaia-geometry.json; ../helper-audit.md; ../SHA256SUMS.json. Original cutout retained at [local path omitted] Historical pipeline definitions are [local path omitted] and [local path omitted] No historical evidence overwritten.

Stable review key: R401. Deciding evidence and catalogue coverage. The export manifest maps original hashes to sanitized files. Analysis scripts are archival and require the recorded external data; local paths are omitted.

Direct public evidence: measured events, raw eclipse plots, raw flux windows, Gaia geometry, independent audit, difference image.

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 168917716: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 7 distinct eclipse events in selected sectors[14, 74, 82]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 5 same-kind midtimes give P=13.4024383530 +/-0.0000718553d, reference eclipse epoch BTJD1699.2149087, kind: Selected alternating eclipse; even half-period cycles; depth parity nearly equal, orbital identity informed by Gaia. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S41 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation1.800arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.666. Capable neighbours: Gaia 2072042036374420736: 16.82 arcsec, G15.817, required fractional eclipse0.581; Gaia 2072040558905683072: 41.98 arcsec, G16.071, required fractional eclipse0.730; Gaia 2072040352747228672: 44.54 arcsec, G14.587, required fractional eclipse0.198; Gaia 2072042105093927936: 52.14 arcsec, G15.474, required fractional eclipse0.428; Gaia 2072040558905685632: 54.35 arcsec, G15.169, required fractional eclipse0.327; Gaia 2072040348430214784: 56.78 arcsec, G13.458, required fractional eclipse0.081; Gaia 2072040558905691648: 58.77 arcsec, G15.239, required fractional eclipse0.348
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths17.954/18.356/16.103ppt, with 4 stacked events. QLP selected-kind fitted median16.506ppt. This separately extracted cutout is an alternative reduction of the same TESS

photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.

5. **Gaia orbital geometry: pass with stated limitations.** DR3207204183021598336O, P=13.4010756298+/-0.0017605164d, e=0.043450, omega=234.1643deg. Closest edge-on conjunction offset0.196176d (0.014639phase), full-SB1-covariance linear propagated Gaia uncertainty0.189543d at the measured epoch. Near-Gaia-reference projected eclipse offset0.062630d (photometric period projection allowance0.007042d). The approximate central duration12.09h vs observed median4.68h is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Shallow repeating eclipses across S14/74/82 with nearly equal alternating depths. Photometry supports6.701d repetition; selected even cycles give13.40244d consistent with Gaia orbit. Equal depths alone cannot reject half-period orbital identity; retained doubled branch explicitly uses Gaia and eclipse parity, with primary identity unresolved. Deficit0.086pixel versus nearest capable neighbor0.859pixel.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

TIC 156103314: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 9 distinct eclipse events in selected sectors[14, 41, 74]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 9 same-kind midtimes give P=8.1521424200 +/-0.0000185155d, reference eclipse epoch BTJD1691.0673712, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S40 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation3.626arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.140. Capable neighbours: Gaia 1129836918680283008: 36.63 arcsec, G14.967, required fractional eclipse0.510
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths32.550/31.110/29.172ppt, with 4 stacked events. QLP selected-kind fitted median31.470ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR31129836845665117312, P=8.1517909446+/-0.0005995836d, e=0.151241, omega=286.0880deg. Closest edge-on conjunction offset0.030193d (0.003704phase), full-SB1-covariance linear propagated Gaia uncertainty0.085527d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.026043d (photometric period projection allowance0.002962d). The approximate central duration8.41h vs observed median6.18h

is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Repeated flat-bottom eclipses across S14/41/74 with stable31-32ppt depth. Target deficit0.173pixel versus capable neighbor1.864pixels.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

R404. TIC 140340353

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 140340353: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 13 distinct eclipse events in selected sectors[33, 87]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 13 same-kind midtimes give P=3.3434088582 +/-0.0000031883d, reference eclipse epoch BTJD2203.1906137, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S33 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation0.867arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.174. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths43.911/42.702/41.059ppt, with 8 stacked events. QLP selected-kind fitted median45.287ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3332271761078881088O, P=3.3440197736+/-0.0003574652d, e=0.098550, omega=327.8916deg. Closest edge-on conjunction offset-0.167185d (-0.049995phase), full-SB1-covariance linear propagated Gaia uncertainty0.161169d at the measured epoch. Near-Gaia-reference projected eclipse offset0.164542d (photometric period projection allowance0.001731d). The approximate central duration6.07h vs

observed median3.22h is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Thirteen narrow eclipses across S33/87 repeat coherently. No capable listed neighbor. Gaia conjunction offset-0.05phase (-0.167d) compared with full-covariance0.161d uncertainty: association is physically consistent within orbital-epoch uncertainty, without arbitrary phase veto.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

R405. TIC 143467555

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 143467555: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 22 distinct eclipse events in selected sectors[19, 59, 86]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 13 same-kind midtimes give P=4.2735185639 +/-0.0000041911d, reference eclipse epoch BTJD1820.1507383, kind: Deeper eclipse; odd historical half-period cycles. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S59 deficit peak[7, 8] vs target pixel[7, 8]; deficit-target separation4.348arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.339. Capable neighbours: Gaia 177237602207452544: 30.18 arcsec, G13.098, required fractional eclipse0.536
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths105.058/86.319/73.841ppt, with 11 stacked events. QLP selected-kind fitted median162.430ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3177237602207451008, P=4.2735828118+/-0.0002613483d, e=0.016118, omega=94.3267deg. Closest edge-on conjunction offset-0.015015d (-0.003513phase), full-SB1-covariance linear propagated Gaia uncertainty0.072119d at the measured epoch. Near-Gaia-reference projected eclipse offset0.006508d (photometric period projection allowance0.001404d). The approximate central duration4.96h vs observed median3.70h is a radius/minimum-mass illustration, not a detailed

binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Unequal alternating depths persist across S19/59/86: odd deeper events about145/167/162ppt versus even76/82/84ppt. Only13 odd deeper measured events define4.27351856d orbital period; half-period aliases are rejected by persistent parity morphology. Target deficit0.207pixel; mixed-kind historical difference stack still locates the signal.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 57358968: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 7 distinct eclipse events in selected sectors[45, 71, 72]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=7.4961579330 +/-0.0000213829d, reference eclipse epoch BTJD2528.4204021, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S45 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.927arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.637. Capable neighbours: Gaia 3365438142952202496: 58.97 arcsec, G13.277, required fractional eclipse0.350
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths80.702/75.505/59.984ppt, with 3 stacked events. QLP selected-kind fitted median91.699ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3336542638762309657 6, P=7.4952754576+/-0.0007670721d, e=0.474132, omega=152.8161deg. Closest edge-on conjunction offset0.050735d (0.006769phase), full-SB1-covariance linear propagated Gaia uncertainty0.220431d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.200771d (photometric period projection allowance0.006094d). The approximate central duration4.94h vs observed median3.69h

is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Seven deep V-shaped eclipses across S45/71/72 with multiple consecutive local cycles; target-localized difference core and capable-neighbor geometry support attribution.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

TIC 348302938: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 14 distinct eclipse events in selected sectors[61, 88]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 14 same-kind midtimes give P=3.6439561479 +/-0.0000165768d, reference eclipse epoch BTJD2966.8369124, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S88 deficit peak[8, 8] vs target pixel[8, 7]; deficit-target separation5.678arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.501. Capable neighbours: Gaia 5724552009498100864: 23.97 arcsec, G15.762, required fractional eclipse0.105; Gaia 5724552211356494720: 25.07 arcsec, G16.345, required fractional eclipse0.178; Gaia 5724552005198026112: 45.97 arcsec, G17.629, required fractional eclipse0.573; Gaia 5724551940778622464: 56.93 arcsec, G17.131, required fractional eclipse0.364
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths2.496/2.706/2.806ppt, with 8 stacked events. QLP selected-kind fitted median4.557ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR35724552009498098432, P=3.6439522672+/-0.0003950777d, e=0.097407, omega=267.6439deg. Closest edge-on conjunction offset-0.047381d (-0.013003phase), full-SB1-covariance linear propagated Gaia

uncertainty0.314984d at the measured epoch. Near-Gaia-reference projected eclipse offset-0.050125d (photometric period projection allowance0.011720d). The approximate central duration4.73h vs observed median2.37h is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Fourteen shallow narrow V-shaped eclipses repeat in S61/88; individual depths scatter at several ppt noise. Deficit0.270pixel from target versus nearest capable neighbor1.107pixels. Consecutive cycles constrain recurrence; parity depths are consistent within noise. Nearly equal primary/secondary events could leave a doubled orbital alias photometrically ambiguous; Gaia supports the retained branch.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

R408. TIC 451086560

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 451086560: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 8 distinct eclipse events in selected sectors[10, 64, 100]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 7 same-kind midtimes give P=8.3004291559 +/-0.0000091255d, reference eclipse epoch BTJD1576.7194332, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S37 deficit peak[8, 7] vs target pixel[8, 7]; deficit-target separation2.006arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.985. Capable neighbours: Gaia 5346004174848323200: 32.54 arcsec, G13.548, required fractional eclipse0.780; Gaia 5346004106128831488: 59.25 arcsec, G8.021, required fractional eclipse0.155
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths68.641/16.758/6.125ppt, with 3 stacked events. QLP selected-kind fitted median151.848ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3534600417484830771 2, P=8.2999349364+/-0.0006655746d, e=0.019055, omega=57.1282deg. Closest edge-on conjunction offset0.133686d (0.016107phase), full-SB1-covariance linear propagated Gaia uncertainty0.089273d at the measured epoch. Near-Gaia-reference projected eclipse offset0.063012d (photometric period projection allowance0.001305d). The approximate central duration8.37h vs observed median6.96h

is a radius/minimum-mass illustration, not a detailed binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Deep flat-bottom eclipses repeat in S10/64/100. Partial S64 cycle179 ingress is excluded from timing. Aperture dilution and changing baseline can contribute to depth variation; deficit0.096pixel from target versus nearest capable neighbor1.679pixels. Adjacent S100 cycles directly test8.30d recurrence. A doubled orbital alias with equal eclipse kinds is not ruled out by parity alone; Gaia supports the retained branch.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

Sector	Historical photometric cycle	Measured midpoint BTJD	Timing error d	Fitted depth ppt	Timing status

R409. TIC 229308711

physical_verdict: CONFIRMED

novelty_status: no identified prior EB

completion: COMPLETE_BOUNDED_REVIEW

next_check: Optional precision characterization

Archived source: sanitized report text.

TIC 229308711: CONFIRMED

Full bounded review: COMPLETE. Physical outcome and catalogue novelty are separate. This review applies current section2.7 and does not promote the historical screening label automatically.

1. **Raw events: pass.** Free trapezoid fits to quality-zero raw QLP SAP_FLUX contain 4 distinct eclipse events in selected sectors[6, 71]. The representative raw-event plot and numeric raw-windows.csv were inspected. The raw morphology, ingress/egress and local baselines were inspected independently of fitted curves; target-specific interpretation follows below. Local linear baseline, free depth, center, duration and ingress were fitted; QLP detrended flux is not used as the deciding raw check. Representative selection is at most three spread available QLP sectors, with coverage/window requirements recorded by the script. Uncovered or flagged windows were never called nulls.
2. **Eclipse timing: pass.** 4 same-kind midtimes give P=14.6174947319 +/-0.0000862147d, reference eclipse epoch BTJD1471.0933055, kind: Selected repeating eclipse; deeper/secondary identity not independently established. Partial or singular center-covariance fits flagged timing_usable=false are excluded from ephemeris and remain documented in measurements.json. Historical event coordinates in difference-image JSON were predictions and are not used as measured timings. Cycle counts were seeded by historical photometric search period, then fit freely across the selected baseline. This is not a blind all-alias search. Error meaning: Linear timing fit using conservative per-event max(formal trapezoid covariance error, half cadence); covariance inflated when reduced chi square exceeds one. Not calibrated coverage or total uncertainty; pipeline timing offsets, trapezoid shape and baseline model systematics are not calibrated.
3. **Target attribution: pass at TESS image resolution.** Historical S6 deficit peak[7, 7] vs target pixel[7, 7]; deficit-target separation2.484arcsec. Full saved difference image, original cutout identity and capable neighbours were audited. PSF-scaled image fractional residual0.289. Capable neighbours: None within60arcsec under the approximate G-band flux-budget test.
4. **Alternative reduction: pass.** Background-subtracted target-centered TESScut aperture gives 1x1/3x3/5x5 depths15.273/15.231/13.308ppt, with 2 stacked events. QLP selected-kind fitted median27.974ppt. This separately extracted cutout is an alternative reduction of the same TESS photons, not independent observing occasions. Dilution, aperture differences and, where relevant, mixed primary/secondary stacks prevent a claim of equal intrinsic depths.
5. **Gaia orbital geometry: pass with stated limitations.** DR3332794035974048076 8, P=14.6215831706+/-0.0049952480d, e=0.028473, omega=271.7243deg. Closest edge-on conjunction offset-0.249469d (-0.017062phase), full-SB1-covariance linear propagated Gaia uncertainty0.546625d at the measured epoch. Near-Gaia-reference projected eclipse offset0.053076d (photometric period projection allowance0.006380d). The approximate central duration18.67h vs observed median12.78h is a radius/minimum-mass illustration, not a detailed

binary fit. Full covariance and assumptions are in gaia-geometry.json. No arbitrary sigma veto is used.

Deciding limitations and interpretation: Four long flat-bottom eclipses repeat in consecutive pairs in S6 and71. Curved/sloped out-of-eclipse variability and asymmetric troughs limit simple trapezoid midtimes. The timing fit allows scatter inflation when needed (none applied here), but does not include total shape systematics. Historical custom pixel stack confirms target deficit0.118pixel; no capable listed neighbor. Consecutive pairs test recurrence and long-baseline cycle count. Equal eclipse kinds could conceal a doubled orbital alias; Gaia supports the retained branch.

Next check: Optional resolved photometry or updated spectroscopy for improved binary parameters; no missing bounded admission check.

Catalogue novelty: central seven-group result applies; see ../../catalogues/coverage-matrix.csv. A separate source in the search cone does not establish a target match. This physical report does not assert exhaustive literature priority.

Measured events (errors are the conservative fit inputs, not calibrated coverage):

TIC 379251709 - CONFIRMED

Unique count addition: yes.

Secondary fold-level, not localized; primary securely on target. QLP/SPOC secondary phases differ 2.6 sigma. Radius tension retained.

Catalogue scope: not in VSX/Gaia-EB/PrÅia/IJspeert/ASAS-SN within 60"; SIMBAD SB*

Full source report

TIC 70665829 - CONFIRMED

Unique count addition: no.

Already objects.csv A4; blind control independently recovered. Archive Gaia-VEB/varisum/SB9 controls failed on later mirror timeout, predecessor empty cones only. No addition.

Catalogue scope: not in VSX/PrÅia/IJspeert within 60"

Full source report; existing A4 evidence

TIC 331293467 - CONFIRMED

Unique count addition: yes.

Heavy blend; QLP plus independent own TESScut satisfies available pipeline check; depths model-dependent 80-116 ppt, ratios/duration agree. Gaia geometry depends on covariance. Gaia-VEB/varisum/SB9 cones lack successful positive controls; no exhaustive novelty claim.

Catalogue scope: not in VSX/PrÅia/IJspeert within 60"; Gaia-EB/varisum/SB9 cones from predecessor run only (mirror timed out)

Full source report

TIC 283532878 - CONFIRMED

Unique count addition: yes.

Use successful s12d recheck, not false-empty first archive pass. Known EB 29.7 arcsec away at P 1.7975 d excluded as source; up to 3 ppt contamination possible. Phase drift tentative.

Catalogue scope: not in VSX/Gaia-EB/PrÅia/IJspeert on target; **a catalogued EB (Gaia DR3 2202301140233408128, P 1.7975 d, G 17.66) sits 29.7" away**, excluded as source but may add â‰¤3 ppt dips

Full source report

TIC 407877153 - CONFIRMED

Unique count addition: yes.

Secondary pixel signal weak individually but summed delta chi2 >=166; QLP depth diluted. Use successful s12d catalogue rerun; all-catalogue query unreliable.

Catalogue scope: not in VSX/Gaia-EB/PrÅia/IJspeert within 60"

Full source report

TIC 15855794 - CONFIRMED

Unique count addition: yes.

Exclude flagged E124 from primary pixel stack as report does. Catalogue positive controls succeeded; catalogue absence only within searched scope.

Catalogue scope: not in VSX/Gaia-EB/PrÅia/IJspeert within 60"

Full source report

TIC 92881948 - CONFIRMED

Unique count addition: yes.

VSX ROT/Gaia SOLAR_LIKE is prior variable classification, not prior EB; catalogue positive controls succeeded. QLP dilution explains shallower depth.

Catalogue scope: VSX lists it as ROT (Gaia DR3 variable) only; not in any EB catalogue

Full source report

TIC 468827621 - CONFIRMED

Unique count addition: yes.

Primary localized in two sectors both camera 2; secondary untested in pixels and neighbour could supply in worst case. Literature search skipped, though catalogue cones performed; known Gaia short-timescale variable is not prior EB.

Catalogue scope: not in VSX/Gaia-EB/PrÅia/IJspeert/SB9 within 60"; SB*

Full source report

TIC 416285595 - CONFIRMED, with caveats

Unique count addition: yes.

Returned CONFIRMED with caveats: QLP/SPOC s40 61.7 vs 54.7 ppt (~12%, ~4 sigma); TESScut depth unreliable. Secondary not pixel-tested; geometry weak/covariance-dependent. Catalogue cones performed but literature search skipped. Report itself says strict depth agreement would imply PROBABLE; no new stricter tolerance imposed here.

Catalogue scope: not in VSX/Gaia-EB/PrÅia/IJspeert/SB9 within 60"; SB*

Full source report

TIC 372683900 - ELLIPSOIDAL

Unique count addition: no.

Smooth double wave, no narrow eclipse; unresolved 1.8 arcsec neighbour; Gaia eccentricity conflicts at 3.3 sigma.

Catalogue scope: Enumerated catalogue cones only; SIMBAD SB* for first four; no exhaustive literature novelty claim. QLP only, one pixel sector per star.

Full source report

TIC 13106408 - ELLIPSOIDAL

Unique count addition: no.

Smooth double wave; nearby 364-day SR unrelated.

Catalogue scope: Enumerated catalogue cones only; SIMBAD SB* for first four; no exhaustive literature novelty claim. QLP only, one pixel sector per star.

Full source report

TIC 372683622 - ELLIPSOIDAL

Unique count addition: no.

Double wave plus variable spots; no eclipse.

Catalogue scope: Enumerated catalogue cones only; SIMBAD SB* for first four; no exhaustive literature novelty claim. QLP only, one pixel sector per star.

Full source report

TIC 319185391 - PLAUSIBLE

Unique count addition: no.

Fold-only ~1 ppt dip, individual events ~1 sigma, dip not pixel-tested, no second pipeline. Report prose says probable-level but batch summary says PLAUSIBLE at best; adopt batch summary outside count. Gaia 434-day astrometric orbit suggests triple.

Catalogue scope: Enumerated catalogue cones only; SIMBAD SB* for first four; no exhaustive literature novelty claim. QLP only, one pixel sector per star.

Full source report

TIC 62328710 - NEIGHBOUR_SIGNAL

Unique count addition: no.

Delta Scuti-like signal localized to Gaia DR3 2165710355333626240 at 44 arcsec and independently seen there by ZTF; target flat at Gaia period; suspect SB1 orbit is interpretation.

Catalogue scope: Enumerated catalogue cones only; SIMBAD SB* for first four; no exhaustive literature novelty claim. QLP only, one pixel sector per star.

Archived detailed period-fold analyses

vet01 full report

Archived source: sanitized report text.

vet01: adversarial check of TIC 195865529 (ATO J310.7264+43.3062) and TIC 468181994 (UCAC4 023-009594)

Opus 5.5 subagent, 2026-10-30, for Fable 5.1. A first agent ran `s1–s8a` and was killed by a container restart. This run kept its downloads and outputs, checked its logs and continued with `s8–s17`. Everything is in `/home/user/eclipses-paper-review/work/c9a-vets/vet01/`. Downloads are in the scratchpad at `data/vet01/<tic>/`; the TESScut cubes were deleted after use. Depths are in ppt, times in BTJD (BJD_TDB − 2457000), durations in hours. A = conjunction at ν = 90° − ω, when the companion is in front of Gaia's RV star. B = ν = 270° − ω.

TIC 195865529: CONFIRMED. A detached F-star + K-dwarf eclipsing binary at the Gaia period. It is already a catalogued EB in ASAS-SN (II/366, EA, P = 3.8310 d) and ATLAS (class DBH at P/2), though not in VSX. - (1) Individual events: 48 primaries and 49 secondaries were re-measured one by one from raw QLP SAP (QUALITY==0). Another 3 primaries were fitted but excluded as partial. - (2) Period: P_ecl = 3.8310456 ± 0.0000009 d, which is −0.15σ from Gaia's. - (3) Pixels: the deficit is on the target in all 8 sectors, across 4 camera/CCD orientations. Every Gaia neighbour within 90″ is excluded by the

pixels. The dilution arithmetic alone excludes all but one: the G 13.46 star at 36″ would need ≈ 100%. - (4) Independence: QLP SAP, my TESScut aperture and TASOC agree after correcting for each aperture's dilution: undiluted primary 183 / 192 / 196 ppt, secondary 48 / 51 / 47 ppt. - (5) Geometry: the primary is conjunction A (A within 0.18σ, B excluded at 3.3–3.9σ). The secondary sits at phase 0.49999 ± 0.00007; Gaia's e and ω predict 0.479 ± 0.024 (+0.87σ). - The screen was right about depths (≈ 185 / 48 ppt), phases and period. Those depths are on QLP's apparently deblended scale, though. Raw apertures see the same eclipse diluted: 127–144 ppt in my r = 1.5 px aperture and 71 ppt in TASOC, whose header gives 64% contamination.

TIC 468181994: CONFIRMED. This is the weaker of the two; see the caveats. A late-F/G star with an M-dwarf-mass companion (m2 sin i ≈ 0.21–0.24 M⊙). It is not in VSX, Gaia-EB, Prša or IJspeert within 60″. - (1) Individual events: 37 primaries were re-measured individually in QLP SAP (one more was excluded as partial), plus 7 in TESScut sector 66, which QLP does not cover. The 1.3 ppt secondary was measured at fixed shape in 39 windows: 37 are positive and 28 are above 2σ. - (2) Period: P_ecl = 3.9969190 ± 0.0000006 d, which is **−2.31σ** from Gaia's 3.999219 ± 0.000996 d. This is the weakest link. - (3) Pixels: the 2.85″ neighbour (G 16.75) cannot be excluded by arithmetic (it would need 73% primary and 4.1% secondary depths). The difference images reject it: the mean centroid over 8 sectors lies 0.51″ from the target and 3.2″ from the neighbour (≈ 16σ), and the PSF χ^2 prefers the target in every sector. Every other G < 18 neighbour is excluded by arithmetic. - (4) Independence: QLP SAP, my TESScut aperture and ELEANOR-lite agree, at 21–24 ppt per sector. - (5) Geometry: the secondary sits at phase 0.4956 ± 0.0012, and Gaia predicts 0.534 ± 0.040 (A) or 0.466 ± 0.040 (B), both within 1σ. Propagated forward with Gaia's P, the primary's absolute phase does not decide between A and B (1.2σ vs 0.7σ). Propagated back with the eclipse P, A is preferred (0.01σ vs 2.2σ). - The screen was right (≈ 23 ppt, ≈ 1.5 ppt near 0.5, P 3.9969 d). The secondary is measurably *before* phase 0.5, at 0.4956. Its depth is 1.24–1.41 ppt. - Gaia shows RUWE 12.6 and ipd_frac_multi_peak = 39%: probably an unresolved sub-arcsecond companion, which TESS pixels cannot test.

1. Archives and web

- **Cones** (`s2_archives.out`, `s2b_archives.out`; the VizieR mirror was sanity-checked on Algol, which returned β Per):
- 195865529:
  - VSX (60″): only `Gaia DR3 2066587835904958592`, type YSO, 15.34–15.39 mag, at **35.76″**. That is the G 15.36 neighbour, not the target.
  - Not in Prša+2022, IJspeert+2021, Gaia DR3 VEB (I/358/veb), Gaia varisum (10″) or SB9.
  - **ASAS-SN II/366 at 0.16″: ASASSN-V J204254.34+431822.5, Type EA, Per 3.8310 d, Amp 0.12 mag, Prob 1.000.**
  - **ATLAS J/AJ/156/241 at 0.09″: class DBH (P(DBH) = 0.98), period 1.915571 d (= P/2).**
  - **So it is already a catalogued eclipsing binary**, though not in VSX.
- 468181994: no rows in VSX, J/ApJS/258/16, J/A+A/652/A120, I/358/veb, I/357/varisum, B/sb9, ATLAS or ASAS-SN II/366 (radii 10–60″, as listed in the scripts).
- The all-catalogue 5″ query returned only astrometric/photometric tables (I/...) for both stars.
- **SIMBAD (harvard mirror, 10″ cone):** both are type SB*, with 1 bibcode each: ATO J310.7264+43.3062 and UCAC4 023-009594. "TIC " is not a SIMBAD identifier for either star (`s2c_simbad_raw.out`).
- **ExoFOP:** tois = [], ctois = [] for both.

- **WebSearch** on all names: nothing mentions either star (`s15_websearch.out`).
- **Gaia DR3 extras** (`s10_gaia_extra.out`):
- 195865529: RUWE 0.94, ipd_frac_multi_peak 0, rv_amplitude_robust 147 km/s (2K1 = 132), Teff_gspphot 6608 K, FLAME R = 2.03 R⊙, M = 1.50 M⊙.
- 468181994: **RUWE 12.57, astrometric_excess_noise 1.53 mas (sig 2803), ipd_frac_multi_peak 39**, rv_amplitude_robust 52.9 km/s (2K1 = 44.7), Teff_gspphot 5775 K, logg 4.08, FLAME R = 2.91 R⊙ (FLAME uses the gspphot distance of 608 pc; the parallax distance is 1044 pc).
- The 2.85″ neighbour 6342991943947141504: G 16.75, BP−RP 1.51, parallax 1.717 ± 0.048 mas, RUWE 1.10.
- The NSS orbit rows match targets.csv. conf_spectro_period = 1.0 for both.

2. Independence, systematics, pixels

- **Pipelines available.** Neither star has TESS-SPOC FFI light curves or 2-min SPOC data (`s1_download_lc.out`).
- 195865529: QLP s15/41/55/56/75/76/82/83, plus TASOC for s15.
- 468181994: QLP s12/13/27/39/67/93/94, plus GSFC-ELEANOR-LITE for s12/13. TESScut covers s66, where QLP has nothing.
- My own photometry: an 11×11 TESScut cube per sector. Background = per-cadence median of the faintest 20% of pixels; aperture r = 1.5 px (6–8 px); QUALITY == 0 (`s8_pixels.py`).
- **Depth method.** One method for every pipeline (`s11_depths.out`): ephemeris and shape fixed, a quadratic baseline per event, and an exposure-supersampled trapezoid amplitude.

TIC 195865529 primary / secondary (ppt)	s15	s41	s55	s56	s75	s76	s82	s83
QLP SAP	182.0 / 49.2	186.2 / 48.2	182.5 / 46.7	182.2 / 46.9	184.3 / 49.2	183.8 / 48.3	182.4 / 48.4	181.9 / 47.6
TESScut ap., raw	141.2 / 38.6	134.7 / 36.0	143.1 / 37.4	127.4 / 33.5	140.9 / 38.1	143.0 / 38.8	129.6 / 34.3	143.5 / 38.0
TESScut ÷ target fraction	183.3 / 50.2	188.1 / 50.3	194.4 / 50.8	197.4 / 51.9	187.2 / 50.6	186.0 / 50.5	204.2 / 54.1	197.5 / 52.3
TASOC raw (AP_CONT 0.637)	71.3 / 16.9 → undiluted 196.2 / 46.5							

- Typical errors are 0.3–0.9 ppt.
- In `s12_dilution.out`, the target's flux fraction in my aperture is 0.635–0.770 from TIC Tmag and the fitted PSF width, and 0.585–0.803 from the fitted scene.
- Undiluted TESScut depths: mean primary 192.3 (sd 7.2), secondary 51.3 (sd 1.4), S/P 0.267. QLP: 183.2 (sd 1.5) / 48.1 (sd 0.9), S/P 0.262.
- So QLP SAP behaves as if it were deblended with the TIC contamination ratio (0.367). The TESScut and TASOC numbers agree with it to ≈ 5%, which is the accuracy of my Gaussian-PSF dilution model. Depth *ratios* agree to 2%.
- Note: the raw aperture depths of this star are not comparable across pipelines without that correction.
- **TIC 468181994 primary (ppt):**
- QLP SAP: 21.0, 22.3, 23.7, 23.2, —, 23.0, 23.3, 21.2.
- TESScut: 22.3, 21.8, 21.9, 22.3, 22.3 (s66), 22.4, 22.8, 22.0.
- ELEANOR-lite raw: 24.3 (s12), 22.7 (s13). ELEANOR-lite corr: 23.4, 22.4.

- These are sectors 12, 13, 27, 39, 66, 67, 93, 94. The target fraction in my aperture is 0.952–0.960.
- Secondary per sector: QLP 1.07–1.55, TESScut 0.96–2.28 (s67 ± 0.98), ELEANOR-lite 0.94–1.61, all with errors of 0.16–0.46.
- All pipelines agree within about 2σ.
- **Difference images** (`s8_pixels_*.out`, `s9_pixsummary.out`). Each is the median out-of-eclipse frame minus the median in-eclipse frame, primaries only. 50 primaries per star went into the stacks, covering all 8 sectors of each. A free-position Gaussian PSF was fitted, and the zero point is a scene model of the out-of-eclipse image (TIC stars with T < 17). Errors come from bootstrapping over events. Two single-event difference images per sector are also listed.
- **195865529:**
  - Per-sector offsets from the target: 1.2–4.3″. Single events: 1.0–4.3″. Sector mean (+0.20 ± 0.57, +1.37 ± 0.91)″.
  - The nearest G < 18 neighbour is 18.9″ away. The difference centroid lies 17–23″ from it (≥ 101σ in every sector) and 32–40″ from the 33–36″ group.
  - PSF hypothesis χ^2: the target is best in all 8 sectors. The next best, the 18.8″ star, is worse by $\Delta\chi^2 \geq 16{,}096$.
  - Arithmetic, as the depth each star would need: the G 13.46 star at 36.0″ has a maximum flux fraction of 18.0%, so it would need 101.6% (primary) and 26.5% (secondary). It is excluded only marginally by arithmetic, but cleanly by pixels. Every other G < 18 neighbour within 90″ would need ≥ 393%.
  - The TIC's T 18.3 star at 10.7″ (G 19.5) contributes about 0.1% and is irrelevant.
- **468181994:**
  - Per-sector offsets: 0.41–1.53″. Mean (+0.50 ± 0.20, −0.12 ± 0.19)″, error from the scatter between sectors.
  - The 2.85″ neighbour is at (–1.67, +2.22)″. Per sector, the difference centroid is 2.3–3.8″ from it (7–24σ); the mean is ≈ 3.2″, or ≈ 16σ.
  - PSF hypothesis $\Delta\chi^2$ (neighbour minus target): +119, +190, +184, +230, +58, +14, +44, +256, so the target is preferred in all 8 sectors.
  - Arithmetic: the neighbour's flux fraction is 3.0–3.1%, so it would need **73.3% / 4.1%**, which arithmetic cannot exclude. All others (44–86″) would need ≥ 293% for the primary.
  - Figures: `fig_468181994.png` and `fig_195865529.png` (out-of-eclipse image, difference image, raw fold). In both, the difference image peaks on the target pixel.
- **Common mode:** not done with other QLP stars. A dip that repeats strictly on one ephemeris across 8 sectors over 6 years, and whose per-pixel difference image follows the target PSF only, is not a sector-wide systematic.
- **Blind period search** on raw SAP (`s4_period_search.out`, BLS 0.5–20 d): the best peaks are 3.83107 d and 3.99694 d. The other peaks are aliases (P/2, 2P, 3P, 4P).

3. TIC 195865529 (P 3.831 d)

Raw QLP SAP, QUALITY==0. Each event is fitted with a trapezoid times a quadratic baseline, with red-noise β-scaled errors (`s6_events.out`). Summary per sector (`s17_tables.out`); every event is listed in `events_table_195865529.md`.

Event	Mid BTJD (range)	Depth (ppt, mean / sd)	T14 / T23 (h)	pipelines

- **Ephemeris and O−C** (`s7_ephem.out`): 48 primaries give P = 3.8310456 ± 0.0000009 d and T0 = 3346.226971 ± 0.000140. Red. χ^2 is 9.43 (errors scaled) and the O−C rms is 1.31 min; sector means lie between −3.4 and +1.8 min.
- **Secondaries:** P = 3.8310460 ± 0.0000013 (P_sec − P_prim = +0.0000004 ± 0.0000015). Phase **0.49999 ± 0.00007**, so e cos ω = −0.00002 ± 0.00010. The durations are equal (T14 5.22 vs 5.25 h), so e sin ω ≈ 0 as well. The orbit is circular.
- **Comparison with Gaia:** P_ecl − P_Gaia = −0.000058 d = −0.15σ.
- **Odd/even primaries:**
- Raw: 182.72 ± 0.21 vs 183.04 ± 0.24 ppt. Sector-normalised: 0.9985 ± 0.0011 vs 1.0021 ± 0.0013 (−2.0σ, driven by the depth differences between sectors).
- Odd/even secondaries: 47.81 ± 0.19 vs 47.60 ± 0.18.
- A distinct 48 ppt secondary at phase 0.5 rules out 2P and P/2.

4. TIC 468181994 (P 3.997 d)

Same method (`s6_events.out`). Every primary is listed in `events_table_468181994.md`; the individual secondaries at fixed phase and shape are in `s7b_sec468.out`.

Event	Mid BTJD (range)	Depth (ppt, mean / sd)	T14 / T23 (h)	pipelines

S, 39 windows s12–s94, phase fixed at 0.4956	1630.867–3877.136	weighted mean 1.24 ± 0.07 (χ^2r 2.54)	primary shape	QLP (TESScut and ELEANOR per sector, §2)

- **Ephemeris** (`s7_ephem.out`): 37 primaries give P = 3.9969190 ± 0.0000006 d and T0 = 2384.303949 ± 0.000146. Red. χ^2 0.75, O–C rms 1.07 min.
- **Comparison with Gaia:** P_ecl – P_Gaia = −0.002300 d = **−2.31σ**.
- **Odd/even:** raw 22.18 ± 0.16 vs 22.55 ± 0.17 ppt; sector-normalised −1.79σ.
- **Secondary:**
- Fold fit: phase 0.4953 ± 0.0006, depth 1.41 ± 0.09 ppt. With the shape free: 0.4952 ± 0.0005, 1.39 ± 0.09 ppt, T14 3.57 ± 0.21 h (`s7_ephem.out`).
- **Null boxes** at phases 0.25 and 0.75: −0.25 ± 0.09 and −0.01 ± 0.09 ppt. The formal errors therefore understate the systematics by up to ≈ 3×. Even so, the secondary stands at ≈ 5σ against the worst null.
- It is present in both halves: s12–39 phase 0.4951, 1.27 ± 0.11 ppt; s67–94 phase 0.4956, 1.25 ± 0.11 ppt.
- Per-sector phases run from 0.4881 to 0.4970: mean 0.4941, standard error 0.0012 (`s13_geometry.out`).
- **The by-eye screen did not resolve** that the secondary is ≈ 25 min early, nor that it is ≈ 1.3 ppt rather than 1.5.

Geometry vs Gaia

(`s13_geometry.out`: 20,000 draws of P, Tp, e, ω; e truncated at 0.) - **195865529** (Gaia e = 0.074 ± 0.040, ω = 235 ± 33°, K1 = 66.18): - Primary minus conjunction A: −0.029 ± 0.161 phase with Gaia's P propagated forward over 771.6 cycles; −0.016 ± 0.141 with the eclipse P propagated back. - Primary minus B: +0.496 ± 0.149 and −0.490 ± 0.127, i.e. 3.3σ and 3.9σ. - **So the primary is conjunction A:** the hotter RV star is eclipsed by the companion. - Predicted secondary phase 0.479 ± 0.024, observed 0.49999 (+0.87σ). Gaia's e cos ω = −0.033 ± 0.040 vs 0.0000 ± 0.0001 observed. Gaia's e is a 1.8σ detection, and the eclipses show the orbit is circular. - **Physics:** - f(m) = 0.1141 M⊙, so m2 = 0.84–0.86 M⊙ for M1 = 1.43–1.50, and a = 13.5–13.7 R⊙. - The flat-bottom trapezoid solution (no limb darkening) gives R1 ≈ 1.72 R⊙, R2 ≈ 0.71 R⊙, k = 0.41, ρ1 ≈ 0.46 ρ⊙. That agrees with FLAME's 2.03 R⊙; TIC's 2.83 R⊙ looks too large. - The depth ratio S/P = 0.267 equals a Planck (800 nm) surface-brightness ratio for T2 ≈ 4500 K against 6600 K. A 0.85 M⊙ dwarf would be about 5000–5200 K (ratio 0.40–0.46). This crude check ignores limb darkening and the partial-eclipse geometry; it is roughly consistent, not exact. - The light-time shift of the secondary is 16–17 s. - **468181994** (Gaia e = 0.085 ± 0.084, ω = 20 ± 49°, K1 = 22.35): - Gaia's P error alone amounts to 0.497 d over the 498.9 cycles to TESS. - Primary minus A: forward −0.286 ± 0.233 (1.23σ), back −0.001 ± 0.192 (0.01σ). Primary minus B: forward +0.163 ± 0.240 (0.68σ), back +0.447 ± 0.202 (2.2σ). - **Undecided with Gaia's own P. With the eclipse period, A is preferred at about 2σ.** - Predicted secondary phase 0.534 ± 0.040 if the primary is A, 0.466 ± 0.040 if B; observed 0.4956 ± 0.0012 (−0.96σ or +0.74σ). - Observed e cos ω ≈ −0.0069 ± 0.0019. Gaia gives +0.053 ± 0.066. - The light-time (Rømer) delay is only 39–43 s (0.0001 phase), so the ≈ 25 min offset points to a small real eccentricity. Template or systematic error at the 1.3

ppt level cannot be excluded. - **Physics:** - f(m) = 0.0046 M⊙, so m2 = 0.21–0.24 M⊙ and a = 11.9–12.7 R⊙. - The trapezoid solution gives R1 ≈ 1.47 R⊙, R2 ≈ 0.22 R⊙, k = 0.152, b ≈ 0.50, ρ1 ≈ 0.54 ρ⊙. R2 suits a 0.2 M⊙ M dwarf. - S/P = 0.062 vs a Planck ratio of 0.077 for 3200 K against 5800 K, consistent with occultation of an M dwarf. - Tension: Gaia's photometric size for the primary (FLAME 2.91 R⊙; logg 4.08 implies ≈ 1.8 R⊙) is larger than the eclipse-implied 1.47 R⊙. Light from the suspected sub-arcsecond companion would inflate the photometric radius and dilute the depths.

Ephemerides and next eclipses

(`s14_ephem_next.out`.) BJD_TDB is converted to geocentric UTC with the barycentric light-time correction **removed** (astropy, builtin ephemeris); the uncorrected times differ by ≤ 2.5 min. - **TIC 195865529:** - P = 3.8310456 ± 0.0000009 d; T0 = BTJD 3346.22697 ± 0.00014 = BJD_TDB 2460346.22697. - Next primaries (geocentric UTC): **2026-11-01 15:04, 2026-11-05 11:00, 2026-11-09 06:57** (BTJD 4346.1299, 4349.9609, 4353.7920; ± 0.4 min formal). T14 ≈ 5.2 h, depth ≈ 18% (on QLP's scale). - Secondaries: 2026-11-03 13:02, 2026-11-07 08:59, 2026-11-11 04:56. - **TIC 468181994:** - P = 3.9969190 ± 0.0000006 d; T0 = BTJD 2384.30395 ± 0.00015 = BJD_TDB 2459384.30395. - Next primaries (geocentric UTC): **2026-11-02 07:00, 2026-11-06 06:55, 2026-11-10 06:51** (BTJD 4346.7912, 4350.7881, 4354.7850; ± 0.5 min). T14 ≈ 3.7 h, depth ≈ 2.3%. - Secondaries (phase 0.4956, ± 7 min): 2026-11-04 06:32, 2026-11-08 06:28, 2026-11-12 06:24.

Caveats

- **468181994:**
- RUWE 12.6 and ipd_frac_multi_peak 39% point to a companion within about 1″. The 2.85″ neighbour is probably not the cause, since Gaia resolves it as a separate source; this is my inference, not a measurement. TESS pixels cannot separate a sub-arcsecond companion. The case for the eclipses being on the RV star is that the eclipse period equals the SB1 period to 0.06%.
- That period agreement is only at 2.3σ given Gaia's quoted error. With a 3σ threshold this is a pass; with a 2σ threshold it would make the star PROBABLE.
- Speckle or AO imaging and a few RVs at quadrature (K1 ≈ 22 km/s) would settle it.
- **195865529:** depth comparisons across pipelines depend on my Gaussian-PSF dilution model (≈ 5%). The 36″ G 13.46 star is excluded by the pixels, not by arithmetic.
- **Not done:** the common-mode test with other stars; any light-curve model with limb darkening (the physics above is trapezoid-level). No TESS-SPOC or 2-min data exist for either star.
- **The `s8` pixel analysis cannot be re-run** without downloading the cubes again (`s3_tesscut_dl.py`), because they were deleted per the brief. Its outputs are saved in `pix/`.
- **Inherited fits:** `s6` marked four primaries and one secondary "ok" although their covariance had failed (partial coverage). `s7` and `s17` exclude them from timing; they are labelled partial above.

Files

- **Scripts and logs:**
- `s1_download_lc`, `s1b_download_other`, `s2_archives`, `s2b_archives`, `s3_tesscut_dl`, `s4_period_search`, `s5_fold_scan`, `s6_events`, `s7_ephem`, `s7b_sec468`, `s8a_tic_neighbours`: from the first agent, checked and reused.

`s8_pixels_<tic>.out`.

- **Data products:** `lcio.py`, `events_qlp.csv`, `events_table_<tic>.md`, `ephem.json`, `s11_depths.json`, `fold_<tic>.txt`, `tic_neighbours_<tic>.csv`, `pix/` (aperture light curves, difference and scene images, per-sector JSON), `fig_<tic>.png`.

TIC 195865529: CONFIRMED; P_ecl=3.8310456±0.0000009 d; depth1=183 ppt (QLP, ≈deblended; 192±7 TESScut undiluted); depth2=48 ppt at phase 0.49999±0.00007; pixel: on target; pipelines: 3 (QLP, own TESScut, TASOC); Gaia geometry: pass (primary = conjunction A at 0.1–0.2σ, B excluded at 3.3–3.9σ; circular orbit) TIC 468181994: CONFIRMED (weaker: P_ecl vs Gaia at −2.3σ; suspected sub-arcsec companion); P_ecl=3.9969190±0.0000006 d; depth1=22.5 ppt (QLP) / 23.2 (TESScut); depth2=1.24–1.41 ppt at phase 0.4956±0.0012; pixel: on target (2.85″ G16.75 neighbour rejected at ≈16σ); pipelines: 3 (QLP, own TESScut, ELEANOR-lite); Gaia geometry: pass (secondary phase within 1σ; A vs B undecided with Gaia P, A preferred at ~2σ with eclipse P)

vet02 full report

Archived source: sanitized report text.

vet02: adversarial check of TIC 470235665 (UCAC4 859-013225) and TIC 379251709 (UCAC4 788-006141)

Opus 5.5 subagent, 2026-10-30, for Fable 5.1. A container restart killed the first agent part-way through. This run picked up its outputs (`s1`–`s8`: archives, downloads, raw-SAP event fits, ephemerides, the 379251709 secondary search, Gaia geometry), checked them, and added the missing parts: `s1c` (SIMBAD bibcodes, the 5″ all-catalogue list for 379251709 that `s1b` crashed on), `s9`/`s10` (TESScut pixels and own photometry), `s11` (independence), `s12` (physics, ephemerides), `s13` (secondary-phase drift), `s14` (fold plots) and `s15` (event tables). Scripts and outputs are in this folder. Light curves are in the scratchpad `data/vet02/<tic>/`. Each TESScut cube was deleted after use. Depths are in ppt and times in BTJD (BJD_TDB − 2457000). A = the companion passes in front of Gaia's RV star (true anomaly 90° − ω). B = the companion is behind it.

TIC 470235665: CONFIRMED. Every check passed: 1. 25 primaries and 25 secondaries are each re-measured from raw SAP in QLP and TESS-SPOC, sectors 18–85. 2. The eclipse period is 10.326183 ± 0.000002 d, +0.82σ from Gaia's 10.3239 ± 0.0028 d. 3. The difference images in s19 (camera 3) and s79 (camera 4) put the deficit on the target. Its centre is 0.29–0.74″ from the out-of-eclipse centroid. Every neighbour would need an intrinsic depth above 100% even if all its flux fell in the aperture. 4. QLP SAP, TESS-SPOC SAP and my own TESScut aperture all see every event they cover. SPOC and TESScut depths agree to about 1%; QLP is 4% deeper. No 2-min data exist. 5. The primary falls on Gaia conjunction A, −0.07 ± 0.11 d away; B is excluded at 19σ. The secondary phase (0.52275) is +0.7σ from Gaia's prediction. The B/A duration ratio gives e sin ω ≥ 0.17, against Gaia's 0.21 ± 0.05.

The screen got this one right (P 10.3262 d, secondary at phase 0.52). Its depths (128/84 ppt) match QLP. TESS-SPOC SAP and TESScut give 122/81 ppt.

TIC 379251709: CONFIRMED. Every check passed: 1. 18 primaries are re-measured individually. The two in s18 that TESS-SPOC flags are recovered in QLP and in my TESScut photometry. 2. The eclipse period is 12.323912 ± 0.000007 d, −0.53σ from Gaia's 12.3261 ± 0.0042 d. 3. The primary deficit

is on the target in s18 (camera 2) and s52 (camera 4), 0.10″ and 1.86 ± 0.65″ from the out-of-eclipse centroid. All neighbours are excluded for the primary even in the worst case. 4. QLP, TESS-SPOC and TESScut depths agree (34–38 ppt). 5. The primary is at conjunction A (−0.17 ± 0.22 d); B is excluded at 28σ with Gaia's correlations, 4.2σ without. The secondary phase (0.4960 ± 0.0010) is +0.8σ from the 0.471 ± 0.031 that Gaia's e and ω predict.

Weak points: - The 2.5 ppt secondary is detected only in folds: QLP S/N 8.5, TESS-SPOC S/N 3.8. It is too shallow for a pixel test or for the neighbour arithmetic. - The short, V-shaped primary implies a primary radius of about 1.3 R⊙, against the TIC's 1.88 R⊙ (see Caveats).

The screen's 31 ppt primary depth is low by about 15%: the raw-SAP depth is 34–36 ppt (TESScut 36.5–38.1). Its period and secondary phase are right.

1. Archives and web

- **VizieR cones, 60″ (`s1_archives.out`):** VSX (B/vsx/vsx), Prša+2022 (J/ApJS/258/16), IJspeert+2021 (J/A+A/652/A120), Gaia DR3 EBs (I/358/veb), Gaia DR3 variability summary (I/357/varisum), Gaia vclassre, SB9 and ASAS-SN II/366 return **0 rows for both stars**. The same query returns 1 row for Algol, so the cones work. Neither star is a catalogued eclipsing binary: none is listed in VSX, Gaia-EB, Prša or IJspeert within 60″.
- **All-catalogue 5″ list (`s1b`, `s1c`):** only astrometric and photometric I/ catalogues come back (47 and 51 tables). The mirror's list stops alphabetically inside I/, so this query is not a completeness check; the targeted cones above are.
- **SIMBAD (`s1_archives.out`, `s1c_archives.out`):**
- 470235665 = UCAC4 859-013225, type **SB***, 1 bibcode (Gaia DR3), RV −66.6 ± 9.2 km/s.
- 379251709 = UCAC4 788-006141, type **SB***, 1 bibcode, RV −34.0 ± 4.0 km/s.
- **ExoFOP:** 0 TOIs and 0 CTOIs for both.
- **Web search:** the 2MASS, UCAC4 and TIC names return nothing relevant for either star.
- **Gaia DR3 orbits (`gaia_nss_tap.csv`):**
- 470235665: SB1, P 10.32387 ± 0.00280 d, e 0.210 ± 0.051, ω 90.3 ± 13.7°, K1 47.5 ± 3.8 km/s, flags 8192.
- 379251709: SB1, P 12.32612 ± 0.00417 d, e 0.097 ± 0.049, ω 122.6 ± 26.8°, K1 23.0 ± 1.1 km/s.
- **TIC stellar parameters (`s1c_archives.out`):**
- 470235665: contamination ratio 0.059; Teff 5353 K, R 2.30 R⊙, log g 3.68.
- 379251709: contamination ratio 0.041; Teff 5279 K, R 1.88 R⊙, log g 3.85.

2. Independence, systematics, pixels

- **Pipelines (`s11_independence.out`, raw SAP, QUALITY==0, trapezoid on a quadratic baseline):**
- 470235665 primary: QLP 127.4 ppt (sd 2.6, N = 23); TESS-SPOC 122.4 (sd 2.0, N = 15); TESScut r ≤ 1.5 px aperture 122.1 ± 0.3 (s19) and 123.3 ± 1.0 (s79).
- 470235665 secondary: QLP 84.0 (sd 1.6); TESS-SPOC 80.9 (sd 1.5); TESScut 80.8 ± 0.3 and 80.9 ± 0.7.
- QLP/SPOC depth ratio over the shared sectors: 1.040 ± 0.007 (primary) and 1.038 ± 0.006 (secondary). This is an aperture/background systematic, much larger than the 0.5 ppt formal errors. TESS-SPOC and TESScut agree within 1%.

- 379251709 primary: QLP 34.2 (sd 3.1, N = 17, including the noisy s24/s25); TESS-SPOC 36.3 (sd 1.4, N = 4); TESScut 38.1 ± 0.8 (s18) and 36.5 ± 0.1 (s52).
- T14 agrees between pipelines: 6.44 h (QLP) vs 6.45 h (SPOC) for the 470235665 primary, 9.02 vs 9.01 h for its secondary, and 4.05 vs 4.22 h for the 379251709 primary.
- Neither star has 2-min SPOC data.
- **Common mode (`s10_offtarget.out`):** this uses off-target pixels inside each cutout instead of other QLP stars.
- Summed over pixels more than 3 px from the target, the stacked primary deficit is –1.1 to +3.2 ppt, against 120 or 33–38 ppt on target.
- The brightest off-target pixels are stars beyond 90″ at the cutout edges, some brighter than the targets. They show –4.2 to +2.2 ppt.
- The eclipses also repeat on a strict period over 6 years, in three cameras and two cadence regimes. A sector-wide systematic cannot do that.
- **Census of non-eclipse dips (`s4_census.out`):**
- Apart from the eclipses, the 4–9 ppt features in raw SAP sit within about 0.3 d of gaps.
- TESS-SPOC s18 starts with a ramp (27–54 ppt, 1790.7–1791.5) **in both stars**, so it is a systematic.
- 379251709 QLP s24 is dominated by scattered light (σ30 = 8.1 ppt). Its events are kept but carry large errors.
- **Difference images (`s9_tesscut_<tic>_s<sec>.txt`; median in-eclipse minus median local out-of-eclipse, per event, averaged; Gaussian-fit centres; 21″/px):**

Star / sector (camera)	kind	N ev	deficit – OOT centroid	deficit – target WCS	frac. depth on target pixel
470235665 s19 (cam 3)	P / S	3 / 2	0.29″ (±0.37) / 0.28″ (±0.14)	0.96″ / 0.96″	122.9 / 76.6 ppt
470235665 s79 (cam 4)	P / S	3 / 3	0.33″ (±0.22) / 0.74″ (±0.26)	1.43″ / 1.58″	120.8 / 77.7 ppt
379251709 s18 (cam 2)	P	2	1.86″ (±0.65)	1.30″	33.2 ppt
379251709 s52 (cam 4)	P	2	0.10″ (±0.46)	1.32″	31.3 ppt

The 379251709 secondary difference images (s18: 2 events; s52: 1 event at the sector start) are noise. No pixel location is claimed for the secondary. - **Dilution arithmetic** (aperture r ≤ 1.5 px; fluxes from Gaia G). The "worst case" puts 100% of the neighbour's flux in the aperture. - **470235665:** the nearest neighbour is G 16.39 at 5.5″, on the target pixel. It would need an intrinsic depth of 320–356% for the primary and 210–234% for the secondary (PRF and worst-case values, both sectors). G 16.19 at 57″ needs at least 269% / 176%; G 15.51 at 69″ needs at least 149% / 98%. That last 98% (s79 secondary) is the only worst case below 100%. That star lies 70″ from the deficit centre, the fractional depth at its pixel is 2.8–8.6 ppt, and it is excluded for the primary. All neighbours are **excluded**. - **379251709 primary:** the brightest neighbour is G 16.57 at 67″ and needs at least 109–128% in the worst case. The nearest is G 17.33 at 30″ and needs at least 216–253%. All neighbours are **excluded**. - **379251709 secondary:** with a 2.5 ppt depth, any neighbour with a worst-case share above about 2.5% could produce it arithmetically. This is not excluded by pixels. It rests on timing: the dip sits exactly at the occultation phase the primary's e cos ω demands. - ZTF was not needed: for the primaries, no neighbour is arithmetically viable.

3. TIC 470235665 (P 10.3262 d)

Raw SAP, QUALITY==0, supersampled trapezoid on a local quadratic baseline, errors max(covariance, prayer-bead) (`events_470235665.csv`, `s5_events.py`). "TESScut" is my own aperture photometry (`s9`) with the shape fixed.

Event	Sector	Mid BTJD	Depth QLP / SPOC / TESScut (ppt)	T14 / T23 (h)	pipelines
P E0	18	1795.7429 ± 0.0003	131.2 / 124.2 / –	6.44 / 2.51	QLP+SPOC
P E1	18	1806.0694 ± 0.0003	128.0 / 121.8 / –	6.45 / 2.60	QLP+SPOC
P E2	19	1816.3945 (TESScut)	– / – / 122.5	(fixed)	TESScut (QLP lost, SPOC partial)

Not measured (gap / flagged / too little coverage): pri E22 (s26, pred 2022.918): QLP lost, SPOC lost; pri E93 (s53, pred 2756.079): QLP lost, SPOC lost; pri E159 (s78, pred 3437.608): QLP partial; pri E177 (s85, pred 3623.479): QLP lost; sec E-1 (s18, pred 1790.822): SPOC partial; sec E0 (s18, pred 1801.148): QLP lost, SPOC lost; sec E15 (s24, pred 1956.041): QLP partial, SPOC partial; sec E90 (s52, pred 2730.506): QLP lost, SPOC lost; sec E144 (s73, pred 3288.121): QLP partial

Period (`s6_period.out`): - Primaries, one value per epoch: N = 25, **P = 10.326183 ± 0.000002 d**, T0 = 1795.74233 ± 0.00018, O–C rms 0.9 min (reduced χ^2 3.5; errors scaled). - Fitting QLP alone and TESS-SPOC alone gives the same P (10.326182). - Secondaries: N = 25, P = 10.326173 ± 0.000002 d. - Joint fit: P = 10.326180 ± 0.000001 d, secondary phase **0.52275 ± 0.00002**. - Gaia P differs by **+0.82σ**.

Odd/even: primary QLP 127.66 ± 0.75 vs 128.24 ± 0.85 ppt (−0.5σ); primary SPOC +1.0σ; secondary +0.02σ / +0.28σ. The two eclipse kinds differ in depth (127 vs 84 ppt) and duration (6.44 vs 9.02 h), so the true period is not twice this one, and the odd/even test rules out a stacked P2.

Shape (`s14_fold_470235665.png`): both eclipses have rounded bottoms. The trapezoid "T23" (2.45 / 2.81 h) is not a resolved flat bottom, so totality is not established.

Secondary-phase drift (`s13_secphase_470.out`): P_sec − P_pri = (−10.0 ± 2.8) × 10^{-6} d (−3.5σ), which would be −2.6 min over 178 cycles. In QLP the secondary phase goes 0.52284 → 0.52277 → 0.52269 across 2019–20, 2022 and 2022–24. TESS-SPOC shows no change between 2019–20 and 2022 (0.52281 vs 0.52280). This hints at apsidal motion or a cadence effect. It is not claimed.

Period (`s6_period.out`): - One value per epoch: N = 18, **P = 12.323912 ± 0.000007 d**, T0 = 1961.25375 ± 0.00060, O–C rms 3.1 min. The largest residuals are +9.2 and +7.2 min, in the noisy QLP s25. - QLP alone: 12.323905 ± 0.000009 d. TESS-SPOC alone (N = 4): 12.323931 ± 0.000018 d. - Gaia P

differs by **−0.53σ**.

Odd/even: QLP 33.87 ± 1.04 vs 34.73 ± 1.27 ppt (−0.5σ); SPOC −0.55σ.

Shape: V-shaped, T14 4.1–4.2 h, trapezoid T23 about 1.0 h.

Secondary (`s7_secondary_379.out`; primaries masked, 1.5-d running median, box scan over phase): - QLP, excluding s24/s25: the strongest peak in the scan is at phase 0.4955. A trapezoid fit gives **phase 0.49597 ± 0.00035, depth 2.47 ± 0.29 ppt (S/N 8.5), T14 4.50 ± 0.43 h**. - TESS-SPOC: 0.49741 ± 0.00040, 2.59 ± 0.68 ppt (S/N 3.8), 2.6σ apart in phase from QLP. The SPOC scan's top peak (phase 0.2235) is the s18 start-of-sector ramp (`s7b_otherpeaks_379.out`). - Individual events (excluding the noisy QLP s24): 1.1–4.1 ppt at S/N 1.6–7.3. Only s59 E78 (4.12 ± 0.56 ppt) is individually significant.

Geometry vs Gaia

`s8_geometry.out`: Monte Carlo with 20000 draws using Gaia's corr_vec. Parameter order is assumed to be P, Vcm, K1, e, ω, Tp. The column-major upper triangle gives a positive-definite matrix with ω–Tp = 0.98–0.99; the row-major one does not. Uncorrelated draws are shown in brackets. `s12_physics_ephem.out` repeats the calculation with nominal values as an independent check.

- **470235665:**
- Taking the TESS ephemeris back to the Gaia epoch, the primary is −0.068 ± 0.108 d from **conjunction A** [−0.080 ± 0.427] and +5.09 d from B (+19σ [+7.5σ]). Taking Gaia's ephemeris forward to TESS gives +0.245 ± 0.405 d from A. The nominal check in `s12` gives −0.079 d.
- Because ω ≈ 90°, conjunction A falls at periastron. The primary is the companion transiting the RV star.
- Gaia predicts the secondary at phase 0.4994 ± 0.0329; measured 0.52275, **+0.71σ**. TESS-only e cos ω ≈ +0.036 vs Gaia −0.001 ± 0.051.
- T14(B)/T14(A) = 1.397 gives e sin ω ≥ +0.166, against Gaia +0.205 ± 0.050. The eclipse at periastron (A) is the shorter one, as the orbit requires.
- **379251709:**
- Backward: the primary is −0.170 ± 0.224 d from **conjunction A** [−0.189 ± 1.218] and −5.96 d from B (−28σ [−4.2σ]). Forward: −0.473 ± 0.418 d from A.
- Gaia predicts the secondary at 0.4711 ± 0.0314; measured 0.4960 ± 0.0010, **+0.79σ**. TESS e cos ω ≈ −0.006 vs Gaia −0.045 ± 0.049.
- Duration ratio 1.066 gives e sin ω ≥ 0.03 vs Gaia +0.068 ± 0.041. This test is weak.
- **Physics (`s12_physics_ephem.out`; rough two-sphere model without limb darkening):**
- **470235665:**
  - f(m) = 0.107 M⊙, so m2 = 0.64–0.77 M⊙ for M1 = 0.93–1.3 M⊙ and a = 23.2–25.4 R⊙.
  - The depths imply k ≈ 0.37 and a companion light share ≥ 8%. The two T14 values with Gaia's e and ω give R1/a = 0.079 and b_A ≈ 0.45, so R1 = 1.8–2.0 R⊙ (TIC 2.30), R2 = 0.67–0.73 R⊙ and i ≈ 87°.
  - J ≈ 0.66, so T2 ≈ 4800 K.
  - A subgiant with a K-dwarf companion: radius, temperature and mass agree with the mass function to about 15–20%. b_B ≈ 0.70 > 1 − k says the B eclipse is partial, which fits the rounded secondary.
- **379251709:**
  - f(m) = 0.0153 M⊙, so m2 = 0.28–0.35 M⊙ (an M dwarf, R2 ≈ 0.3–0.4 R⊙).

- Read as a non-grazing transit (T23/T14 = 0.22), the shape needs b ≈ 0.77 and **R1 ≈ 1.2–1.5 R⊙, R2 ≈ 0.25–0.30 R⊙**, which is consistent with m2. With the TIC's R1 = 1.88 R⊙ the 4.2 h eclipse would have to be grazing (b ≈ 0.99), and that is hard to square with a 36 ppt depth.
- A 3200–3500 K companion would give a full-occultation depth of 4–8 ppt; the measured secondary is about 2.5 ppt. Consistent.

Ephemerides and next eclipses

From `s12_physics_ephem.out`. The barycentric light-time correction (+2.8 to +5.2 min) was removed to give UTC at the geocentre. Errors are formal, from T0 and P. - **TIC 470235665 primary:** T0 = BTJD 1795.74233 ± 0.00018 (BJD_TDB 2458795.74233), **P = 10.326183 ± 0.000002 d**, T14 6.45 h. - Next primaries: BTJD 4346.3095 = **2026-11-01 19:21 UTC**; 4356.6357 = **2026-11-12 03:11**; 4366.9619 = **2026-11-22 11:00** (±0.8 min). - Secondary: T0 = 1801.14120 ± 0.00023, P = 10.326173 ± 0.000002 d, T14 9.0 h. Next: 2026-11-07 04:52, 2026-11-17 12:42, 2026-11-27 20:31 UTC. - **TIC 379251709 primary:** T0 = BTJD 1961.25375 ± 0.00060 (BJD_TDB 2458961.25375), **P = 12.323912 ± 0.000007 d**, T14 4.2 h; secondary at phase 0.4960 ± 0.0010. - Next primaries: BTJD 4352.0927 = **2026-11-07 14:07 UTC**; 4364.4166 = **2026-11-19 21:53**; 4376.7405 = **2026-12-02 05:40** (±2.1 min).

Caveats

- **SAP depths depend on the pipeline at the 4% level** (QLP deeper) and none are corrected for crowding (TIC contamination 4–6%). "Agreement" here means within about 5%, not within the formal errors.
- **The 379251709 secondary is a fold-level detection** (QLP S/N 8.5, SPOC S/N 3.8, phases 2.6σ apart). It has not been located in pixels or excluded from neighbours arithmetically. Its exact match to the e cos ω phase is what ties it to the target.
- **379251709 radius tension:** the eclipse shape prefers R1 ≈ 1.3 R⊙, about 30% below the TIC's 1.88 R⊙, unless the eclipse is grazing. This is not a failed check, but the TIC Teff/radius deserves a look. A spectrum, or a proper fit with limb darkening on the 200-s data, would settle it.
- **470235665:** the secondary-phase drift (−2.6 min over 5 years, 3.5σ, seen in QLP only) is unconfirmed. The rough physical model is crude and does not decide whether either eclipse is total.
- **Gaia geometry:** the forward predictions (±0.4 d) are limited by Gaia's P error. The backward test (±0.1–0.2 d) assumes the corr_vec ordering stated above; without correlations the errors grow to ±0.4–1.2 d and B is still rejected at 4.2σ and 7.5σ.
- **TESScut times** are not barycentred to the target, which puts them up to about ±3 min off (O−C −3.1 to +3.0 min). They are not used in any ephemeris.
- **Not done:** the QLP-neighbour common-mode test; TESScut-only sectors 60 and 86 of 470235665, which no pipeline covers; ZTF.

Archived source: sanitized report text.

vet03: adversarial check of TIC 70665829 (UCAC4 537-050325) and TIC 331293467 (UCAC4 150-142995)

Opus 5.5 subagent, 2026-10-30, for Fable 5.1. This run resumed from a predecessor that was killed by a container restart. The predecessor wrote `s1`–`s7` and their outputs. Its pixel run for 331293467 stopped part-way through s100 (`s7_pixels_331293467.out`). I checked those outputs, re-ran the pixel analysis for 331293467 in all four sectors (`s7b`), and wrote `s9`–`s14` plus `s2c`, `s10a`, `s12b`. All scripts, `.out`/`.json` outputs and the `pix_*.png` plots are in this folder. Downloads are under `/tmp/claude-0/-home-user-eclipses-paper-review/55c92ff4-798a-544f-be03-9888c6804905/scratchpad/data/vet03/<tic>/`; the TESScut cubes have been deleted. Notation: **A** = the companion passes in front of Gaia's RV star (true anomaly ν = 90° − ω). **B** = the RV star passes in front of the companion. Depths are in ppt of the raw (undetrended) flux unless marked "undiluted".

TIC 70665829: CONFIRMED. A K dwarf with an early-M companion, P = 3.4657654 d. - **(1) Events, pass:** 24 primaries and 28 secondaries (SPOC), and 22 and 28 (QLP), measured one by one from SAP QUALITY==0 flux. - **(2) Period, pass:** the eclipse period matches Gaia's at −0.43σ. - **(3) Pixels, pass:** the difference images in s46, s48 and s72 (three cameras) sit 0.5–1.2″ from the target. The only neighbour (G 14.44 at 64″) would need an intrinsic depth above 1500%. - **(4) Independence, pass:** QLP, TESS-SPOC, my TESScut aperture photometry and ZTF g/r all see both eclipses. Absolute depths differ by up to ~10% between apertures. The secondary/primary depth ratio is 0.216–0.233 in every pipeline, so the differences are dilution or background, not the signal. - **(5) Geometry, pass:** the secondary falls at phase 0.46048, which is e cos ω = −0.0621. Gaia predicts 0.4547 +0.024/−0.024 if the deep eclipse is A (+0.24σ), and needs 3.6–5.6σ if it is B. The deep eclipse

coincides with conjunction A (+0.4 ± 0.5 h when Gaia's orbit is conditioned on the TESS period). So the deep event is Gaia's RV star (the K dwarf) being eclipsed. ZTF colours agree: the deep eclipse is deeper in g, the shallow one deeper in r. - **Screen:** correct on all points (deep ~300–330 ppt at phase 0, ~65–72 ppt secondary at 0.4605, flat baseline, P 3.4658 d).

TIC 331293467: CONFIRMED. An A/F star with a K-dwarf companion, P = 5.2568199 d. The light is heavily blended, so the undiluted depths are uncertain. - **(1) Events, pass:** 21 primaries and 24 secondaries measured individually from QLP SAP QUALITY==0. Every secondary is above 3σ, and null phases 0.25/0.75 give −0.11 ± 0.16 and −0.09 ± 0.15 ppt. - **(2) Period, pass:** +0.51σ from Gaia. - **(3) Pixels and dilution, pass:** the diff-image source sits 0.3–3.6″ from the target in s38, s99, s100 and s101 (cameras 2, 4, 3, 2). - The G 17.07 star at 8″ needs 305–458%, the G 16.07 at 24″ needs 143–287%, and the G 16.14 at 14″ needs 91–115% (over 100% in s99). All are arithmetically excluded or effectively so. - The only neighbour that passes the arithmetic, G 13.78 at 30.5″ (needs 25–84%), is excluded by position. The fit is 10–19× worse at its position, and the measured offset points 0.00–0.11 of the way toward it. - ZTF has no data at Dec −60. No higher-resolution light curve was available. - **(4) Independence, pass in dilution-free form:** no TESS-SPOC or SPOC light curve exists. My TESScut 3×3 photometry sees every eclipse with the same T14 (4.05–4.08 h against QLP 4.07 h) and a secondary/primary ratio of 0.168–0.202 against QLP 0.160–0.176. Raw depths differ by aperture (QLP 61–73, TESScut 47–56 ppt). The undiluted primary depth is model-dependent: 80–89 ppt from PSF amplitudes, 80–116 ppt from aperture shares. - **(5) Geometry, pass:** the secondary is at phase 0.50013 ± 0.00023 (Gaia predicts 0.5015, so this cannot tell A from B). The deep eclipse sits on Gaia's conjunction A: +0.1 ± 1.0 h when conditioned on the TESS period, and +0.49σ on Gaia alone with correlations. B is excluded at 6.7σ (Gaia alone) or ≫10σ (conditioned). This test needs Gaia's ω–T_p correlation (0.9997); with independent errors it does not decide. Landing on the target's own spectroscopic conjunction is further evidence that the signal is on the target. - **Screen:** the ~66 ppt and ~11 ppt figures are right for QLP SAP. The undiluted target depths are about 8–11% and 1.3–2%.

1. Archives and web

- **Catalogue cones (`s2_archives.py`, 60″, VizieR mirror):**
- 70665829: nothing in VSX, Prsa+2022, IJspeert+2021, Gaia DR3 VEB, Gaia varisum or SB9.
- 331293467: the same, except one VSX entry at 33.7″: Gaia DR3 5866907631080924672, type L, G 18.4–18.63. It is not our star and is fainter than the 90″ neighbour list (G < 18).
- Neither star is a catalogued eclipsing binary within 60″ in these catalogues.
- **Sanity checks:** the VSX cone was checked on Algol (1 row at 0.11″, `s2_archives.out`). `s2c` showed the mirror serves Prsa (nearest EB 1621″ from 331293467) and IJspeert (nearest 2860″ from 70665829). The mirror then began timing out, so Gaia-VEB, varisum and SB9 were not sanity-checked (`s2c_catalogue_sanity.out`). The all-catalogue 5″ query (`s2b`) returned only I/ catalogues, even for Algol, so it is truncated and was not relied on.
- **SIMBAD (10″):**
- 70665829 = UCAC4 537-050325, type SB*, 3 bibcodes (2023A&A...674A..34G, 2022AJ....163..152S, 2022ApJS..259...35A).
- 331293467 = UCAC4 150-142995, type SB*, 1 bibcode (2023A&A...674A..34G).
- **ExoFOP:** no TOIs or CTOIs for either star (`s2b_allcat.out`).
- **Gaia NSS rows (`s10a_gaia_nss.csv`):** both are SB1 with flags 0. corr(ω, T_p) is 0.9984 for 70665829 and 0.9997 for 331293467.

2. Independence, systematics, pixels

- **Pipelines (`s1_download_lc.out`):**
- 70665829: QLP s45, s46, s48, s72; TESS-SPOC s45, s46, s48, s72 and "s1751". MAST labels that last product sector 1751 (camera 1, BTJD 4055.76–4063.00, 1480/3131 good cadences); it is used as given. No 2-min SPOC.
- 331293467: QLP only (s11, s38, s99–s102). No TESS-SPOC and no 2-min data.
- **Per-sector depths, primary / secondary in ppt (`s9_indep.out`):**

TIC / sector	QLP SAP	TESS-SPOC SAP	TESScut 3×3 raw	TESScut / target share	PSF amp / target flux	d2/d1 (QLP, SPOC, TESScut)
70665829 s45	325.3 / 72.3	300.3 / 67.3	—	—	—	0.222, 0.224, —
70665829 s46	306.6 / 66.1	296.2 / 66.6	297.6 / 67.2	325.3 / 73.4 (0.915)	287.5 / 65.8	0.216, 0.225, 0.226
70665829 s48	312.2 / 70.6	282.7 / 64.1	288.1 / 67.1	285.2 / 66.4 (1.010)	264.6 / 60.4	0.226, 0.227, 0.233
70665829 s72	329.8 / 72.2	299.0 / 67.9	300.6 / 66.2	340.8 / 75.0 (0.882)	290.9 / 64.1	0.219, 0.227, 0.220
331293467 s11	61.4 / 9.8	—	—	—	—	0.160
331293467 s38	64.7 / 10.6	—	46.7 / 9.4	80.5 / 16.3 (0.580)	79.6 / 14.2	0.163, —, 0.202
331293467 s99	72.6 / 12.0	—	50.4 / 9.2	115.8 / 21.1 (0.435)	89.3 / 14.6	0.165, —, 0.182
331293467 s100	70.1 / 11.7	—	51.3 / 8.6	99.2 / 16.6 (0.517)	87.5 / 12.7	0.166, —, 0.168
331293467 s101	61.4 / 10.7	—	55.5 / 9.6	106.7 / 18.5 (0.520)	81.5 / 12.1	0.174, —, 0.173
331293467 s102	70.5 / 12.4	—	—	—	—	0.176

- For 70665829, QLP SAP is 4–10% deeper than TESS-SPOC SAP in every sector, but the d2/d1 ratios match. This is a multiplicative aperture or background-scale difference, not a different signal. TESS-SPOC CROWDSAP is 0.966 (s46) and 0.969 (s1751).
- For 331293467, raw depths depend on the aperture (TIC contamination ratio 0.70), while d2/d1 and T14 agree.
- **ZTF (`s13_ztf.out`, 2″ cone):**
- 70665829: 1789 rows from 2018 to 2025 (HJD−2457000 1202.8–3969.0), folded on the TESS ephemeris.
  - Primary core: zg 361 and 316 ppt, zr 325 and 315 ppt (4–8 points per field).
  - Secondary core: zg 26 and −9 ppt, zr 60 and 33 ppt.
  - So the eclipses are seen by an independent instrument, the ephemeris holds back to 2018, and the secondary is redder.
- 331293467: 0 rows (Dec −60, outside ZTF).
- **Common mode:** I did not fetch other QLP stars. Both signals repeat at a fixed period across 3 cameras (70665829) and 3 cameras over 7 years (331293467), with secondaries at fixed phase, and the difference images show no off-target deficit. A sector-wide systematic cannot do that.
- **Blind dip census (`s3_events_*.out`, 5×MAD below a running median; `s11_census.out`):** every dip is a primary or secondary except:
- TESS-SPOC s1751 at 4059.25–4059.7: a ramp from 0.935 to 0.98 right after a data gap (phase 0.77–0.90), background flat.

- QLP s48 at 2621.1–2621.5: QLP background −110 to −210, many cadences flagged 2048/4096.
- Both are systematics.
- **Pixels (`s7_pixels_70665829.out`, `s7b_pixels_331293467.out`):** median in-eclipse minus out-of-eclipse images from the TESScut 11×11 cubes, a PSF-fitted source position, and the dilution needed for every Gaia neighbour within 90″ with G < 18, in a 3×3 aperture (scene model with Gaussian PSF and TIC-style T from G and BP−RP).
- **70665829, primary:** offset 1.0 ± 0.2″ (s46), 1.2 ± 0.6″ (s48), 0.5 ± 0.1″ (s72).
- **70665829, secondary:** 2.3 ± 0.3″, 1.1 ± 0.8″, 1.8 ± 0.1″.
- **70665829, neighbour:** the only one, G 14.44 at 64.3″, needs 7253–47260% (primary) and 1573–10587% (secondary), with a χ^2 ratio of 41–78. Excluded.
- **331293467, primary offsets:** 0.3 ± 0.2″ (s38), 2.0 ± 0.2″ (s99), 1.2 ± 0.3″ (s100), 3.6 ± 0.5″ (s101). Bootstrap errors are surely underestimates of the systematics, but every offset is far smaller than any separation that matters.
- **331293467, neighbour by neighbour:**
  - G 17.07 at 8.0″: needs 377/458/334/305%. χ^2 ratio 3.6–4.6. Offset projection onto it is 0.03/0.23/0.00/−0.18 of the way.
  - G 16.14 at 14.0″: needs 91/115/99/97%. χ^2 ratio 3.8–10.5. Projection −0.01/0.01/−0.08/0.24.
  - G 16.07 at 24.4″: needs 143–287%.
  - G 13.78 at 30.5″: needs 84/45/28/25%, so not excluded by arithmetic. χ^2 ratio 19.1/10.1/19.1/16.0 and projection 0.00/−0.00/0.04/−0.11, so excluded by position.
  - G 14.73 at 47.3″: needs 96–5754%, χ^2 ratio 10–20.
  - All other neighbours need more than 150%.
- **331293467, secondary:** the fit gives 0.2 ± 0.7″, 1.9 ± 1.0″, 3.2 ± 0.6″, 3.2 ± 1.3″. The χ^2 cannot separate the target from the 8″ and 14″ stars here (ratio ~1.0–1.1), and a G 12.85 VARIABLE star at 89.4″ on the cutout edge fits the secondary diff image better (ratio 0.14–0.36). That star contributes 0.0000 of the aperture flux, so it is noise in a 4–5 event average, not a source. The secondary is tied to the target because it keeps a fixed phase (0.5002) and a fixed d2/d1 with the on-target primary.

3. TIC 70665829

Measurements (raw SAP QUALITY==0; trapezoid with quadratic baseline; `s3_events_70665829.out` lists every event). Sector summaries:

Event	Mid BTJD (first … last)	Depth (SPOC / QLP / TESScut)	T14 / T23	pipelines
Primary s45 ×6	2528.21356 … 2549.00771	300.3 / 325.3 / —	2.83 / 0.53 h (all SPOC primaries; range 2.80–2.90)	SPOC, QLP
Primary s46 ×6	2555.93930 … 2576.73431	296.2 / 306.6 / 297.6	"	SPOC, QLP, TESScut
Primary s48 ×6	2611.39079 … 2635.65071 (2614.85610 SPOC only)	282.7 / 312.2 / 288.1	"	SPOC, QLP, TESScut
Primary s72 ×5	3262.95482 … 3283.74972	299.0 / 329.8 / 300.6	"	SPOC, QLP, TESScut
Primary s1751 ×1	4060.08215 ± 0.00010	299.86	2.84 / 0.53 h	SPOC
Secondary s45 ×7	2526.34374 … 2547.13826	67.3 / 72.3 / —	2.77 / 0.54 h (all SPOC secondaries; range 2.57–2.88)	SPOC, QLP
Secondary s46 ×8	2554.07007 … 2578.32973	66.6 / 66.1 / 67.2	"	SPOC, QLP, TESScut

Event	Mid BTJD (first … last)	Depth (SPOC / QLP / TESScut)	T14 / T23	pipelines
Secondary s48 ×6	2612.98690 … 2633.78190	64.1 / 70.6 / 67.1	"	SPOC, QLP, TESScut
Secondary s72 ×6	3264.54980 … 3285.34512	67.9 / 72.2 / 66.2	"	SPOC, QLP, TESScut
Secondary s1751 ×1	4061.67233 (partial, egress lost)	54.78	—	SPOC

- **Lost events:** in TESS-SPOC, s45/46/48/72 lose 1/2/5/4 events to gaps (`s11_census.out`). QLP flags more of s48: it has 1 full and 11 partial events there.
- **Period (`s12_ephem.out`, full-coverage events, joint fit):**
- SPOC: T0 = 2791.61111 ± 0.00009 BTJD, P = 3.4657654 ± 0.0000007 d. QLP: 3.4657623 ± 0.0000006 d.
- The 3σ difference comes from the single s1751 primary. Without it, SPOC primaries give 3.4657637 ± 0.0000012, and the s1751 eclipse arrives +2.30 min late (`s12b_no1751.out`).
- Primary O−C has χ^2_r of 24–30 against the formal errors: sector means range from −1.9 to +1.3 min (s48 is early in both pipelines while its secondaries are not). This was not pursued, but the realistic timing error is about ±2 min.
- Gaia P = 3.4658878 ± 0.0002846, so $(P - P_{Gaia})/\sigma = -0.43$ for both pipelines.
- **Odd/even (`s4_period_70665829.out`):** primary +0.62 ± 0.82 ppt (SPOC), −0.87 ± 1.24 (QLP). Secondary +0.17 ± 0.54, −1.06 ± 0.74. No difference.
- **Which eclipse is primary:** the primary (300 ppt) and secondary (67 ppt) differ by a factor of 4.5 and sit at an off-centre phase. So P is neither half nor double the true period, and the deeper event is unambiguous.

4. TIC 331293467

Measurements (QLP SAP QUALITY==0. Primaries have a free trapezoid fit (`s3_events_331293467.out`). Secondaries use the primary's shape with free t0 and depth (`s5_secondary_331293467.out`)):

Event	Mid BTJD (first … last)	Depth QLP (TESScut raw)	T14 / T23	pipelines
Primary s11 ×4	1601.23407 … 1622.26045	61.4	4.07 / 0.83 h (all primaries; range 3.93–4.23)	QLP
Primary s38 ×5	2337.18980 … 2358.21445	64.7 (46.7)	"	QLP, TESScut
Primary s99 ×2	4050.91270, 4066.68276	72.6 (50.4)	"	QLP, TESScut
Primary s100 ×3	4077.19684 … 4098.22307	70.1 (51.3)	"	QLP, TESScut
Primary s101 ×4	4103.47964 … 4124.50456	61.4 (55.5)	"	QLP, TESScut
Primary s102 ×3	4129.76349 … 4150.78766 (last one partial)	70.5	"	QLP
Secondary ×24 (3/4/4/5/4/4 per sector)	1603.8613 … 4148.1608	11.42 ± 0.15 weighted mean (8.6–13.4 each)	primary shape (TESScut free fit 3.5–4.2 h)	QLP, TESScut

- **Lost events:** 14 events fall in gaps across the six sectors (`s11_census.out`).
- **Period (`s12_ephem.out`, full-coverage, joint):** T0 = 3467.40446 ± 0.00029 BTJD, P = 5.2568199 ± 0.0000020 d.
- All primaries: 5.2568187 ± 0.0000017. Secondaries only: 5.2568291 ± 0.0000074 (1.4σ).

- Gaia P = 5.2565467 ± 0.0005365, so +0.51σ.
- **Odd/even, primary:** −1.19 ± 0.49 ppt (formal 2.4σ, 1.8% of the depth). It is driven by sectors with 1–2 events and a partial s102 event, and the sector-to-sector depth scatter (61–73 ppt) is much larger. At 2P both halves are the same eclipse type, and the 11 ppt secondary at phase 0.5002 rules out P/2. Not a sign of a wrong period.

Geometry vs Gaia

All from `s10_geometry.out`: 20000 draws each with independent errors, with Gaia's correlation matrix, and with that matrix conditioned on the TESS period.

70665829. Gaia: e = 0.0769 ± 0.0397, ω = 175.4 ± 22.2°, T_p = 390.5724 ± 0.2071 BTJD. - **Secondary phase:** measured shallow-after-deep phase is 0.46048 ± 0.00008. The implied e cos ω = −0.0621, the same exact or to first order. - **Gaia prediction:** (t_B − t_A)/P = 0.4547 (+0.0239/−0.0238). That is below 0.5 in 100% of draws, with e cos ω = −0.0711 ± 0.0362. - Deep = A matches at +0.24σ. Deep = B would need 0.5395, at +3.55σ. - Conditioned on the TESS period: 0.4630 ± 0.0136, giving A −0.19σ and B +5.64σ. - **Absolute timing (630 cycles from T_p):** - Independent errors: deep minus A = −0.0215 ± 0.0999 P (−0.22σ); minus B = −4.71σ. - Gaia correlated: deep minus A = −0.0204 ± 0.0585 P (−1.7 h, −0.35σ); minus B = −11.7σ. - Conditioned on the TESS period: deep minus A = +0.0051 ± 0.0064 P (+0.4 h, +0.80σ); minus B = −56σ. - **Conclusion: deep eclipse = conjunction A.** Gaia's ω decides this through two independent routes (secondary phase and absolute timing). - **Durations:** T14 is 2.77 h for the secondary and 2.83 h for the primary (SPOC). This is consistent with Gaia's small e sin ω = +0.0032 ± 0.0310. - **Physics (`s14_physics.out`, M1 = 0.85 M⊙):** f(m) = 0.0807 M⊙, giving m2 ≈ 0.54 M⊙ (≈3760 K, ≈0.52 R⊙). a = 10.75 R⊙ (a/R1 = 14.2). A central eclipse would last 3.15 h against 2.83 h observed, so b > 0. The expected d2/d1 ≈ J(800 nm) ≈ 0.28 against 0.22 observed. - A cooler M-dwarf companion makes the K dwarf's eclipse the deep one, as the timing says. ZTF agrees: the deep eclipse is deepest in g, the shallow one deeper in r.

331293467. Gaia: e = 0.0215 ± 0.0250, ω = 287.0 ± 69.8°, T_p = 389.8053 ± 1.0004 BTJD. - **Secondary phase:** 0.50013 ± 0.00023 (joint fit) and 0.5002 ± 0.0001 (`s5`). That gives e cos ω = +0.0003 to +0.0004 ± 0.0002, against Gaia's +0.0024 ± 0.0227. Consistent, but it cannot separate A from B. - **Absolute timing (699 cycles from T_p):** - Independent errors: deep minus A = +0.14σ, minus B = −1.90σ. Not decisive. - Gaia correlated: deep minus A = +0.0321 ± 0.0649 P (+4.1 h, +0.49σ); minus B = −6.66σ. - Conditioned on the TESS period: deep minus A = +0.0009 ± 0.0077 P (+0.1 h, +0.12σ); minus B = +81σ. Conditioning shifts T_p by +0.29 d and ω by +20.7°, because corr(P, T_p) = 0.57. - **Conclusion: deep eclipse = conjunction A,** the K dwarf in front of the A/F star. This rests on Gaia's corr(ω, T_p) = 0.9997, which is physically expected at e ≈ 0. - **Physics (M1 = 1.69 M⊙):** f(m) = 0.0630 M⊙, giving m2 ≈ 0.71 M⊙ (≈4580 K, ≈0.70 R⊙, k ≈ 0.41). a = 17.04 R⊙. A central eclipse would last 5.76 h against 4.07 h observed (b > 0). The expected d2/d1 ≈ 0.21 against 0.16 observed. The undiluted primary depth of 8–11% is below $k^2 \approx 0.17$, as a partial or high-b transit should be.

Ephemerides and next eclipses

From `s12_ephem.out`. Times are BJD_TDB / BTJD, converted to UTC calendar dates without the barycentric-to-Earth light-time correction (up to ±8.3 min). - **TIC 70665829:** T0 = 2791.61111 ± 0.00009 BTJD (BJD_TDB 2459791.61111), P = 3.4657654 ± 0.0000007 d (SPOC). The secondary follows at +1.59591 ± 0.00029 d (phase 0.46048). Realistic timing error is ±2 min (see §3). - Next primaries: 4344.2740 (2026-10-30 18:33 UTC), 4347.7398 (2026-11-03 05:44), 4351.2055 (2026-11-06 16:54). The QLP ephemeris is 1–2 min earlier. - Next secondaries: 4345.8699 (2026-11-01 08:51),

4349.3357 (2026-11-04 20:02), 4352.8014 (2026-11-08 07:12). - **TIC 331293467:** T0 = 3467.40446 ± 0.00029 BTJD (BJD_TDB 2460467.40446), P = 5.2568199 ± 0.0000020 d. The secondary follows at +2.62912 ± 0.00123 d (phase 0.50013). - Next primaries: 4345.2934 ± 0.0004 (2026-10-31 19:01 UTC), 4350.5502 (2026-11-06 01:11), 4355.8070 (2026-11-11 07:20). - Next secondaries: 4347.9225 (2026-11-03 10:07), 4353.1793 (2026-11-08 16:17), 4358.4361 (2026-11-13 22:26).

Caveats

- **331293467 has a single pipeline (QLP) plus my own TESScut photometry.** Its undiluted depths rest on a Gaussian-PSF scene model: primary 80–116 ppt (79.6–89.3 ppt from PSF amplitude), secondary ~13–21 ppt. Only the fact that the signal is on the target, the timing and the ratios are robust.
- **Attribution for 331293467 is pixel-level, not resolved.** ZTF has no data at Dec −60. The G 13.78 star at 30.5″ is excluded only by position (and by the timing match to Gaia's conjunction), not by arithmetic. Bootstrap centroid errors (0.2–0.5″) understate the systematics, but the closest call is still 0.24 of the way toward any neighbour.
- **Gaia geometry for 331293467 is decisive only with the corr_vec decoding** (order P, Vcm, K, e, ω, T_p, column-major upper triangle; the 0.9997 ω–T_p term confirms it).
- **70665829 timing:** the O−C scatter between sectors (±1–2 min) and the late s1751 primary (+2.3 min) are unexplained. Candidates are timestamps in the unusual "sector 1751" product, or real timing variations. This does not affect the classification.
- **Archives:** the cones for Gaia-VEB, varisum and SB9 were not checked on a known object, because the mirror failed during `s2c`. Their empty results stand from `s2` only.
- **Common mode:** not done with other stars (see §2).

vet04: adversarial check of TIC 283532878 (UCAC4 740-075601) and TIC 407877153 (UCAC4 054-021425)

Opus 5.5 subagent, 2026-10-30, for Fable 5.1. This run resumed the work of an earlier agent that a container restart killed part-way through. I re-read its scripts and outputs `s01`–`s11` and kept what they had measured. I re-ran the archive step it had not finished (`s12`), and found that the first VizieR pass gave false empty results (see §1). New steps: a difference-image test with real noise weighting (`s13`, `s13b`), because the `s11` "chi2" values were unweighted sums of squares. Also new: ZTF (`s14`), plots (`s15`), a common-mode test (`s16`), extra geometry, physics and ephemeris (`s17`), and a merged event table (`s18`). All of these are in `/home/user/eclipses-paper-review/work/c9a-vets/vet04/`. The downloads are in the scratchpad at `.../scratchpad/data/vet04/<tic>/`. I deleted the TESScut cubes after `s13`. Notation: **A** = the companion passes in front of Gaia's RV star (true anomaly ν = 90° − ω); **B** = the RV star passes in front of the companion. Depths are in ppt, times in BTJD = BJD_TDB − 2457000, durations in hours.

TIC 283532878: CONFIRMED. - (1) Each event fitted on its own in raw QLP SAP flux, QUALITY==0: 11 primaries and 9 full secondaries, plus 1 partial secondary. One more primary (s16, 1744.53) is visible only in TESScut. - (2) The eclipses give P = 17.446019 ± 0.000019 d. Gaia's 17.4298 ± 0.0089 d is +1.83σ away. - (3) Difference images in all 8 sectors (cameras 2, 3 and 4) put both the primary and the secondary on the target. Primary offsets are 0.4–1.5″. Secondary offsets are 1.0–5.3″, each within ~2σ. Every Gaia neighbour is rejected by $\Delta\chi^2 \geq 1119$ for the primary and $\Delta\chi^2 \geq 41.7$ for the secondary in every sector. The dilution arithmetic alone excludes every neighbour for the primary (each would need ≥ 218%). For the 10 ppt secondary it does **not** exclude three neighbours (G 14.50 at 37″, G 14.93 at 28″, G 15.74 at 29.5″, each needing 30–47%); the pixels do. - (4) QLP SAP and my own TESScut photometry agree on the secondary (9–10 ppt in both). For the primary, QLP gives 70–79 ppt and the TESScut aperture 65–72 ppt, with 13–20% of that aperture's light from neighbours. The PSF-deblended depth is 71–77 ppt. No TESS-SPOC or 2-min data exist. - (5) The secondary is at phase 0.67812 ± 0.00030; Gaia's e and ω predict 0.712 ± 0.024 (–1.4σ). The primary falls 0.20 d from Gaia's conjunction A (0.4–0.7σ); B is excluded at > 11σ. - **Screen check:** the screen was right. The "~9 ppt dip near 0.675" is the eccentric secondary. It is not a one-sector glitch: it appears in all 8 sectors and 4 seasons at constant phase (0.6775–0.6795). Its depth is 9–10 ppt; 10–11 ppt deblended.

TIC 407877153: CONFIRMED. - (1) Each event fitted on its own: 9 full primaries and 9 secondaries in raw SAP, plus extra partial events (two primaries, two secondaries). - (2) The eclipses give P = 17.089294 ± 0.000008 d. Gaia's 17.0902 ± 0.0063 d is −0.14σ away. - (3) Difference images put the primary on the target in 6 sectors ($\Delta\chi^2 \geq 337$ against every neighbour). The secondary also fits best on the target in 6 sectors ($\Delta\chi^2 \geq 7$ per sector; ≥ 166 summed over sectors). The arithmetic needs ≥ 441% (primary) and ≥ 51% (secondary) on any neighbour. - (4) Three pipelines: TESS-SPOC SAP (28.6–29.4 ppt), my own TESScut aperture (29.4–31.0 ppt) and QLP SAP. QLP gives 27–29.6 ppt in s12/s39 but

only 24–27 ppt in s93–s102, a QLP dilution issue. The secondary is 2.6–4.2 ppt in all three. - (5) The secondary is at phase 0.54690 ± 0.00017; the prediction is 0.559 ± 0.044 (−0.28σ). The primary is at conjunction A (0.16–0.64σ); B is excluded at ≥ 5σ. - **Screen check:** the secondary is **3.0 ppt, not ~2 ppt** (stack 2.98 ± 0.13). The primary is ~29 ppt in SPOC and TESScut, not ~27 (27 is QLP's diluted value). The phase of 0.545 was right.

1. Archives and web

- **VizieR cones** (`s12d_recheck.out`, mirror vizier.idia.ac.za, run immediately after an Algol VSX control returned bet Per, EA/SD):
- **TIC 283532878** is not in VSX, Gaia DR3 EB (I/358/veb), Prsa+2022, IJspeert+2021, Gaia varisum or SB9 within 60″ of the target. Both VSX and Gaia-EB list one row at **29.6″: Gaia DR3 2202301140233408128**, G 17.66 (the "VARIABLE" neighbour in `neighbours_90as.csv`). It is VSX type E, P = 1.79747 d, G 17.61–18.17; Gaia EB eclipse depths are 0.39 and 0.60 (`s12e_neighbour_eb.out`). It is excluded as the source below.
- **TIC 407877153:** nothing in any of those six catalogues within 60″.
- **First-pass warning:** the first pass (`s12_archives.out`) returned 0 rows everywhere, including the EB above, and its Algol control failed later (`s12c_controls.out`: VSX 0 rows for Algol). The mirror was intermittently returning empty tables. The all-catalogue 5″ query is likewise unreliable here: its Algol control gave 0 tables (`s12b_archives.out`), so I do not use it.
- **SIMBAD** (sim-coo 10″, `s12b_archives.out`): both stars are type **SB*** with 1 bibcode (2023A&A...674A..34G, the Gaia DR3 NSS paper). TIC 283532878 = UCAC4 740-075601 = 2MASS J21512860+5759057. TIC 407877153 = UCAC4 054-021425 = 2MASS J18230801-7921092.
- **ExoFOP:** no TOI. "CTOIs 0" on both pages.
- **Conclusion:** neither star is a catalogued eclipsing binary within 60″. Both are known only as Gaia SB1s.

2. Independence, systematics, pixels

- **Pipelines:**
- 283532878: QLP SAP (8 sectors) plus my own TESScut aperture photometry (8 sectors). The two agree on the secondary. The primary is shallower in my aperture because it holds 13–20% neighbour light (`s11_pixels_283532878.out`: target fraction 0.796–0.873).
- 407877153: QLP, TESS-SPOC (s12, s13, s39) and TESScut. SPOC and TESScut agree on the primary to about 1 ppt; QLP s93–s102 are ~10–15% shallower. No 2-min SPOC data exist for either star.
- **Difference images, noise-weighted (`s13_pixnoise_*.out`, `s13b_summary.out`):** in each sector I averaged the per-event (median out − median in) images. The per-pixel noise comes from 300 pseudo-events at random out-of-eclipse times with the same windows. I then fitted Gaussian-PSF single-source models for the target and for every Gaia neighbour with G < 18 within 90″. Results:
- 283532878 P: S/N 40–154 per sector; least-rejected neighbour $\Delta\chi^2$ = 73,292 summed (≥ 1119 in every sector); PSF-amplitude depth on target 70.6–77.3 ppt.
- 283532878 S: S/N 8.6–14.9; $\Delta\chi^2 \geq 41.7$ in every sector, ≥ 977 summed; depth 9.8–12.9 ppt; free-fit offsets 1.0–5.3″ (1σ 1.3–2.9″).
- 407877153 P: S/N 18.6–84; $\Delta\chi^2 \geq 337$; depth 30.0–35.3 ppt.
- 407877153 S: S/N 2.8–8.7; $\Delta\chi^2 \geq 7.1$ per sector, ≥ 166 summed; offsets 3.6–9.9″ with 1σ 1.9–12″.
- I looked at two of the images (`s15_diff_283532878_s57_S.png`, `s15_diff_407877153_s13_S.png`). In both, the deficit sits on the target pixel, away from the bright neighbours in the direct image.

- **Dilution arithmetic** (per-sector aperture flux fractions, `s11_pixels_*.out`):
- **283532878 primary:** every neighbour needs ≥ 218% intrinsic depth, so all are excluded.
- **283532878 secondary (10.2 ppt):** most neighbours are excluded arithmetically (≥ 82% needed; the G 17.66 Gaia EB at 29.7″ needs 181–240%). Three are **not**: G 14.50 at 37.0″ needs 29.6–100%, G 14.93 at 28.3″ needs 30–47%, and G 15.74 at 29.5″ needs 31.8–39%. The difference images reject them instead ($\Delta\chi^2 \geq 41.7$ each sector).
- **407877153:** the primary needs ≥ 441% on any neighbour; the secondary needs ≥ 51.5% (G 14.68 at 60″, s13) and 61–135% for the G 17.23 star at 46″.
- **Same period and phase drift:** both secondaries share the primary's period (283532878: P_S – P_P = −0.00030 ± 0.00010 d; 407877153: +0.000013 ± 0.000059 d, `s05_ephem.out`) and sit at fixed phase over 4–5 seasons. A neighbour's EB would have to share the period exactly. The catalogued neighbour EB (P = 1.7975 d; 17.446/1.7975 = 9.71, not commensurate) would drift in phase.
- **ZTF (`s14_ztf.out`):** not informative. IRSA returns only 54–94 catflags==0 points per object for the target and the five closest bright neighbours, with 0–1 points inside any eclipse window.
- **Common mode (`s16_commonmode.out`):** not done. The MAST product queries kept failing (RemoteServiceError and proxy resets, `s16_commonmode.out`), and the coordinator then dropped this optional step. The pixel and two-pipeline evidence above stands without it.
- **Phase 0.5 of 283532878** (`s17_geometry2.out`, from 10 fixed-time fits in `s08`): +0.35 ± 0.30 ppt. There is no eclipse at phase 0.5. $\chi^2 = 45/9$ shows red noise at the ~2–3 ppt level.

3. TIC 283532878 (P = 17.446 d, e = 0.35)

Measurements (`s18_event_table.out`, from `s04`/`s08`/`s11`; trapezoid with quadratic baseline, raw SAP QUALITY==0; "fixed" means the shape is fixed from the 200-s stack). There is no TESS-SPOC column because this star has no TESS-SPOC data.

- **Stacked shape** (200-s QLP, `s08_shape_oddeven.out`):
- Primary: 75.41 ± 0.39 ppt, T14 = 7.028 ± 0.034 h, T23 = 2.08 ± 0.05 h. This is a near-V shape: a grazing or partial eclipse.
- Secondary: 10.24 ± 0.40 ppt, T14 = 6.66 ± 0.25 h, T23 = 2.78 ± 0.36 h.
- **Period** (`s05_ephem.out`):
- 11 primaries alone: P = 17.446025 ± 0.000017 d (χ^2 = 56/9; O–C within ±7 min). 9 secondaries alone: 17.445724 ± 0.000099 d.
- The joint fit gives P = 17.446019 ± 0.000019 d, +0.0162 d from Gaia's period = **+1.83σ_Gaia**.
- The cycle count is unambiguous: consecutive primaries within s56, s57 and s77 are 17.44 d apart.
- **Odd/even** (QLP fixed shape): 76.25 ± 0.38 vs 75.36 ± 0.33 ppt. The difference is 1.8σ, smaller than the 1.5–2.6 ppt scatter between sectors. A secondary of different depth exists at phase 0.678, so 2P is ruled out, and phase 0.5 is empty, so P/2 is ruled out.
- **Secondary phase by season** (`s17_geometry2.out`): 0.67954 ± 0.00026 (s16–17), 0.67854 ± 0.00033 (s57), 0.67750 ± 0.00025 (s76–77), 0.67775 ± 0.00016 (s83–84).
- **Physics:** f(m) = 0.0334 M⊙. With the TIC M1 = 1.35 M⊙, m2 ≥ 0.48 M⊙ and a = 34.6 R⊙. The depth ratio S/P = 0.136 implies a TESS-band surface-brightness ratio ≈ T2 3830 K, consistent with an early-M companion with R2 ≳ 0.5 R⊙. A central eclipse at conjunction A would last ~9.5 h; the observed 7.0 h and V shape mean a high impact parameter. The duration ratio S/P = 0.948 ± 0.036 gives e sin ω ≈ −0.03 ± 0.02, against Gaia −0.086 ± 0.044. The equal-b assumption behind that number is weak for grazing eclipses.

4. TIC 407877153 (P = 17.089 d, e = 0.13)

Measurements (`s18_event_table.out`). TESS-SPOC depths are fixed-shape fits where available.

- **Stacked shape** (200-s QLP):
- Primary: 25.53 ± 0.16 ppt (QLP-diluted), T14 = 9.459 ± 0.051 h, T23 = 6.38 ± 0.08 h. **Flat-bottomed**, a total transit.
- Secondary: 2.98 ± 0.13 ppt, T14 = 8.46 ± 0.31 h, T23 = 5.71 ± 0.50 h. **Flat-bottomed**, an occultation.
- **Period:**
- 9 primaries: P = 17.089294 ± 0.000006 d (χ^2 = 6.0/7; O–C within ±2.3 min). 9 secondaries: 17.089307 ± 0.000059 d.
- Joint fit: P = 17.089294 ± 0.000008 d, **−0.14σ_Gaia**.
- Secondary phase by season: 0.54630–0.54713, steady.

- **Odd/even:** TESS-SPOC 28.91 ± 0.31 vs 28.91 ± 0.30 ppt. The QLP odd/even difference (26.10 vs 26.91) comes from which sectors fall in each group: QLP s93+ are diluted. 2P and P/2 are excluded as for the other star.
- **Physics:**
- f(m) = 0.0216 M⊙. With the TIC M1 = 0.87 M⊙, m2 ≥ 0.31 M⊙ and a = 29.5 R⊙.
- The flat-bottom depth gives k ≈ 0.16, so R2 ≈ 0.31 R⊙ with the TIC R1 = 1.91 R⊙. That matches a 0.31 M⊙ M dwarf.
- The occultation/transit ratio of 0.117 gives T2 ≈ 3200 K (TESS-band Planck).
- A central T14 at conjunction A would be 10.6 h; observed 9.46 h, so b is moderate.
- The duration ratio S/P = 0.894 ± 0.033 gives e sin ω = −0.056 ± 0.018, against Gaia −0.078 ± 0.066.
- Everything hangs together as a subgiant + M-dwarf SB1.

Geometry vs Gaia

- **Method** (`s07_geometry.out`, `s17_geometry2.out`; 20,000 Monte Carlo draws): I propagated P, T_p, e and ω; conjunction A is at ν = 90° − ω and B at ν = 270° − ω. The ω–T_p correlation was taken either as 0 or as the last `corr_vec` element (0.927 and 0.985). That second case assumes the SB1 parameter order ends with (arg_periastron, t_periastron), which I have not verified; results are given both ways.
- **283532878:**
- Predicted B–A separation: 0.7122 ± 0.0237. Measured secondary phase: 0.67812 ± 0.00030, **−1.44σ**. The other assignment (primary = B) is off by 16σ.
- The measured phase implies e cos ω = 0.2823 ± 0.0012 (exact Kepler, Gaia e sin ω draws), against Gaia 0.338 ± 0.039 (–1.42σ).
- Absolute timing, propagated with the TESS period: the primary is +0.0112 phase (+0.20 d) from conjunction A (0.37σ uncorrelated, 0.71σ correlated) and 0.30 phase from B (11.9σ / 23.7σ). Propagated with Gaia's period, A is still within 1.7–2.0σ.
- **The deep eclipse is A:** the F-type RV star is eclipsed by its companion. **Pass.**
- **407877153:**
- Predicted separation 0.5589 ± 0.0435; measured 0.54690 ± 0.00017, **−0.28σ**. The other assignment is off by 2.4σ.
- Implied e cos ω = 0.0733 ± 0.0006, against Gaia 0.093 ± 0.068.
- The primary is +0.0167 phase (+0.29 d) from A (0.16σ / 0.64σ) and 5.1σ / 18.9σ from B.
- **The deep eclipse is A**, the subgiant RV star transited by an M dwarf. **Pass.**

Ephemerides and next eclipses

From `s05_ephem_*.json` and `s17_geometry2.out`. UTC times are geocentric: I removed the barycentric light-time with astropy (offset given in brackets). - **TIC 283532878:** T0 = BJD_TDB 2458761.97572 ± 0.00150 (BTJD 1761.97572), **P = 17.446019 ± 0.000019 d**. Secondary T0 = 1773.80624 ± 0.00535 (phase 0.67812). - Next primaries: BTJD 4343.9865 = 2026-10-30 11:36 UTC [+3.4 min]; 4361.4325 = 2026-11-16 22:18; 4378.8785 = 2026-12-04 09:02. Each ±2.3 min formal; T14 = 7.0 h. - Next secondaries: BTJD 4355.817, 4373.263, 4390.709. The secondary phase has moved by ~0.002 between seasons, so allow ±1 h. - **TIC 407877153:** T0 = BJD_TDB 2458634.26184 ± 0.00084 (BTJD 1634.26184), **P = 17.089294 ± 0.000008 d**. Secondary T0 = 1643.60789 ± 0.00296 (phase 0.54690).

- Next primaries: BTJD 4351.4596 = 2026-11-06 23:03 UTC [−3.1 min]; 4368.5489 = 2026-11-24 01:13; 4385.6382 = 2026-12-11 03:22. Each ±1.0 min; T14 = 9.5 h. - Next secondaries: BTJD 4343.716, 4360.806, 4377.895.

Caveats

- **Secondary-phase drift in 283532878:** the phase falls 0.0018 between 2019 and 2024 (≈ 45 min, ~4σ formal), and the joint timing χ^2 is 132/17. GR plus tidal apsidal motion at a/R1 ≈ 18 would give far less (~2.5×10^{-4} rad over 105 cycles, against the ~0.03 rad needed). I therefore treat this as underestimated timing errors for the 10 ppt, red-noise-affected secondaries, not as physics. It does not affect the Gaia test, whose tolerance is ±0.024.
- **Catalogued EB 29.7″ from 283532878:** this is G 17.66, P = 1.7975 d, eclipses 40–60% deep in G. With 0.4–0.6% of the light in my apertures it can add dips of ≤ 3 ppt at unrelated phases. That may explain some event-to-event scatter in the secondary depths (for example S n=105, 12.6 ppt). It cannot produce the secondary: the period is wrong, the depth needed is 181–240%, and the pixels reject it.
- **Gaussian-PSF limits:** the pixel model uses a Gaussian PSF. Formal centroid offsets for the primaries (up to 1.5″ for 283532878; 5.1″ and 7.6″ in s93 and s102 for 407877153, the s102 stack including a partial event) exceed their noise-only errors. That is model systematics; every neighbour is ≥ 26″ away and rejected by $\Delta\chi^2$ in the hundreds or more.
- **Deblended depths are model-dependent:** for 283532878, about 71–77 ppt (PSF amplitude) up to ~80 ppt (aperture depth ÷ target fraction). The TIC contamination ratio is 0.32. QLP's SAP depths for 407877153 in s93–s102 are diluted by ~10–15%.
- **Not used:** ZTF (too few epochs), 2-min SPOC (none exists), TESScut for s101 of 407877153 (not downloaded; QLP covers its two secondaries).
- **Correlation assumption:** the `corr_vec` ordering behind the correlated Monte Carlo case is assumed, not verified. The secondary-phase test does not use T_p at all.

Files

All in `/home/user/eclipses-paper-review/work/c9a-vets/vet04/`: - **Shared code:** `common.py` (loader, Gaia constants), `fitlib.py` (trapezoid fitter). - **Earlier agent, read and kept:** - `s01_download` (QLP/TESS-SPOC light curves); `s02_inventory` (sectors, gaps, flags); `s03_blind` (blind dip census); `s04_events` (+ `.json`, per-event free fits); `s05_ephem` (+ `s05_ephem_<tic>.json`); `s06_gaia_query` (+ `s06_gaia_nss.csv`, `s06_gaia_source.csv`); `s07_geometry` (Monte Carlo conjunctions); `s08_shape_oddeven` (+ `.json`, `s08_stack_*.npz`); `s10_tesscut_dl`; `s11_pixels` (+ `_<tic>.out/.json`, `s11_diff_*.npy`; aperture photometry, dilution). - **This run:** - `s12_archives.out` (first pass, false negatives), `s12b_archives` (SIMBAD by coordinates, ExoFOP), `s12c_controls` (failed Algol control), `s12d_recheck` (cones with passing control), `s12e_neighbour_eb` (neighbour EB rows). - `s13_pixnoise` (+ `_<tic>.out/.json`, `s13_diff_*.npz`), `s13b_summary`. - `s14_ztf`, `s15_plot_diff` (+ `s15_diff_*.png`), `s16_commonmode`, `s17_geometry2`, `s18_event_table`. - **Downloads:** `/tmp/claude-0/-home-user-eclipses-paper-review/55c92ff4-798a-544f-be03-9888c6804905/scratchpad/data/vet04/` (TESScut cubes deleted).

TIC 283532878: CONFIRMED; P_ecl=17.446019±0.000019 d; depth1=75 ppt (QLP SAP; 71–77 deblended); depth2=10 ppt at phase 0.6781; pixel: on target; pipelines: 2 (QLP, own TESScut); Gaia geometry: pass TIC 407877153: CONFIRMED; P_ecl=17.089294±0.000008 d; depth1=29 ppt (TESS-SPOC/TESScut; 25–27 QLP s93+); depth2=3.0 ppt at phase 0.5469; pixel: on target; pipelines: 3 (QLP, TESS-SPOC, own TESScut); Gaia geometry: pass

vet05 full report

Archived source: sanitized report text.

vet05: adversarial check of TIC 15855794 (UCAC4 564-009141) and TIC 92881948 (WISE J053256.98-225927.8)

Opus 5.5 subagent, 2026-10-30, for Fable 5.1. This run resumed from a predecessor that was killed by a container restart; that run had finished s1–s9 and part of s10. This run added s10b/c/d (archives), s11 (own TESScut photometry, difference images, dilution), s12 (master event table, ephemerides), s13 (Gaia geometry MC) and s14 (physics). The coordinator cut the budget, so the report is short. Scripts and outputs are in this folder. Downloads are in the scratchpad `data/vet05/<tic>/`; all TESScut cubes have been deleted. Depths are in ppt, times in BTJD = BJD_TDB − 2457000. "C" = own TESScut photometry with a 3×3 aperture, "Q" = QLP SAP, "S" = TESS-SPOC SAP (QUALITY==0 throughout).

TIC 15855794: CONFIRMED. (1) Repeating events: I measured 12 primaries and 11 secondaries one by one from raw flux. (2) Period: the eclipse period is 5.8911458 ± 0.0000038 d, +0.54σ from Gaia. (3) Pixels: in s44, s70 and s71 the difference-image deficit lies 0.4–0.9″ from the target, and every neighbour is excluded. (4) Pipelines: Q, S and C agree on depth to within 4%. (5) Geometry: the primary falls at Gaia conjunction A (+0.03 ± 0.08 d at the Gaia epoch; conjunction B is excluded at ~40σ), and the secondary phase of 0.50182 matches Gaia's prediction of 0.502 ± 0.021. Corrections to the screen: the primary is 35.3 ppt after dilution correction, not "probably larger", and it lasts 3.25 h. The secondary is 5.0–5.4 ppt.

TIC 92881948: CONFIRMED. (1) Repeating events: 24 primaries and 22 secondaries measured one by one. (2) Period: 8.8049754 ± 0.0000013 d, +0.43σ from Gaia. (3) Pixels: in all 7 sectors the deficit lies 0.3–1.6″ from the target, and the depth scales with the target's flux fraction in the aperture. (4) Pipelines: Q, S and C agree once dilution is accounted for. (5) Geometry: the primary falls at conjunction A (+0.06 ± 0.09 d; B is excluded at ~44σ). The secondary phase is 0.48334 ± 0.00008, so $e \cos \omega = -0.026$, which is 1.0σ from Gaia's prediction of 0.502 ± 0.018. Corrections to the screen: the primary depth is 16.4 ppt (Q) / 18.3 ppt (C) / 19.0 ppt dilution-corrected, not ~11 ppt. It lasts 1.69 h, not the 1.2 h that BLS gave. The secondary is 5.0–5.3 ppt at phase 0.4833.

Not tested for either star: the common-mode test (brief item 8, outside the five protocol checks) and next-eclipse UTC predictions (budget).

1. Archives and web (s10, s10b, s10c, s10d)

- **15855794:** no rows within 60″ in VSX, Prsa+2022 (J/ApJS/258/16), IJspeert+2021, Gaia DR3 vari_eclipsing_binary / I/358/veb, or SB9. It is not in Gaia vari_summary. SIMBAD: SB*, 1 bibcode (2023A&A...674A..34G). ExoFOP: TOIs 0, CTOIs 0.
- **92881948:** VSX has one entry at 1.35″: "Gaia DR3 2964506347485091072", type **ROT**, G 12.76–12.80. Nothing in Prsa, IJspeert, Gaia-EB or SB9. Gaia vari_summary: in_vari_eclipsing_binary = 0; the classifier's best class is SOLAR_LIKE (0.63). SIMBAD: SB*, 1 bibcode. ExoFOP: TOIs 0, CTOIs 0.
- **Neither star is a catalogued eclipsing binary.**

- **Positive controls:** each catalogue cone found a known row (Prsa, I/358/veb, IJspeert and SB9 via control rows; VSX via the 92881948 row itself).
- **Brief error:** the brief lists "I/357/varisum", but Gaia DR3 variability is I/358 (I/357 is the NSS part), so Gaia variability was queried through TAP.

2. Independence, systematics, pixels (s11_*.out, s12_compile.out, s14_physics.out)

- **Depths, 15855794 (all events):**
- Primary: Q 35.84 ± 0.27 (n=11), S 34.56 ± 0.32 (n=4), C 34.90 ± 0.23 (n=12), C dilution-corrected 35.34 ± 0.23.
- Secondary: Q 5.00 ± 0.30, S 4.91 ± 0.43, C 5.36 ± 0.24.
- The C primary χ^2 of 34/11 comes from E124 (27.6 ppt, at the end of the s70 orbit, a cadence QLP flags).
- **Depths, 92881948:**
- Primary: Q 16.43 ± 0.24, S 18.20 ± 0.24, C 18.33 ± 0.18, C r2.5 15.90 ± 0.23. Divided by the modelled target fraction, 3×3 gives 18.99 ± 0.19 and r2.5 gives 19.17 ± 0.28: they agree.
- QLP is shallower because its larger aperture takes in a G 13.67 star (60″) and a G 14.56 star (53″). TESS-SPOC CROWDSAP is 0.90–0.94.
- Secondary: Q 5.02 ± 0.21, S 5.33 ± 0.24, C 5.08 ± 0.18.
- **Difference images** (median of the eclipse core minus median of the flanks, per sector; pixel-integrated Gaussian fit; errors from 200 fake-event stacks):
- 15855794, primary: offsets from the target 0.4″ (s44, 1.1σ), 0.5″ (s70 without E124, 0.8σ; the run including E124 is distorted by that event) and 0.9″ (s71, 2.1σ). Every neighbour is >45″ from the centroid at >100σ. Secondary: 1.2–3.5″, ≤1.0σ.
- 92881948, primary: offsets 1.3″ (s5), 1.6″ (s6), 1.4″ (s32), 0.9″ (s98), 0.3″ (s107), 1.5″ (s108), 0.9″ (s109), all ≤2.8σ, with errors of 0.02–0.06 px. The nearest neighbour is at 29″. In every sector the pixel with the deepest fractional dip is the target pixel or one next to it.
- **Dilution arithmetic** (Gaussian PSF, and a PSF 1.5× broader):
- 15855794: in the 3×3 aperture the brightest neighbour (G 16.03, 45″) contributes ≤1.9% of the flux. It would need an intrinsic depth of ≥180% to make the primary: excluded. All other neighbours contribute ≤0.6%: excluded.
- 92881948: in 3×3, G 13.67 (60″) contributes 0.11–1.44% and would need ≥127%: excluded. G 14.56 contributes ≤3.95% and would need ≥46%; it is not excluded by arithmetic alone, but it is excluded by the centroid (53″ away) and because the depth grows in the smaller aperture. G 16.46 (29″) contributes ≤2.4% and would need ≥75%; it is excluded by the centroid.

3. TIC 15855794 (joint shape fit, s6: P 35.25 ± 0.31 ppt, T14 3.255 ± 0.025 h, T23 0.70 ± 0.03 h; S 4.89 ± 0.38 ppt, T14 3.14 ± 0.19 h)

There is no 2-min SPOC data. The s43 TESScut cut-out is empty (RAW_CNTS = –1, s11_15855794_s43_check.out).

- **Sectors without other pipelines:** sectors 107–109 exist only in TESScut (no QLP or SPOC light curves). There is no 2-min SPOC data.
- **Period:** primaries only, P = 8.8049749 ± 0.0000013 (χ^2 26.8/22). Secondaries only, P = 8.8049820 ± 0.0000049. TESScut alone, P = 8.8049753 ± 0.0000014. All are +0.43σ from Gaia's 8.804360 ± 0.001441.
- **Odd/even primaries:** +1.6σ (S), +0.2σ (Q), +0.7σ (C).
- **Secondaries** are not at phase 0.5 and differ from the primaries in depth, so this is not an equal-pair P/2 system.

Geometry vs Gaia (s13_geometry.out; 20000 draws, NSS correlation matrix)

- **How the test works:** with ω and T_peri correlated at +0.9996, conjunction times are well defined. Without the correlations the prediction is uninformative (σ ≈ 2 d). The order of the first four corr_vec parameters is uncertain, so all 24 orders were run; they give the same answer.
- **15855794:**
- Observed primary minus conjunction A, at the Gaia epoch: +0.030 d (robust σ 0.080; over the 24 orders +0.23 to +0.46σ). Minus conjunction B: −2.93 d (−39σ).

- Carried forward with Gaia's P: +0.65σ.
- Secondary phase: predicted 0.5019 ± 0.0209, observed 0.50182 ± 0.00030; e cos ω = +0.0029 ± 0.0005, against Gaia's +0.003 ± 0.033.
- **92881948:**
- Primary minus conjunction A: +0.060 d (σ 0.086; +0.35 to +0.69σ). Minus conjunction B: −43σ.
- Forward with Gaia's P: +0.52σ.
- Secondary phase: predicted 0.5016 ± 0.0181, observed 0.48334, a 1.0σ difference (32% of draws lie as far from 0.5). e cos ω = −0.0262, against Gaia's +0.003 ± 0.028.
- **Which conjunction:** in both stars the primary is conjunction A, the companion passing in front of the RV star.
- **Physics (s14, uniform discs):**
- 15855794: f(m) = 0.0437 M⊙, so m2 ≥ 0.49 M⊙ (M dwarf, about 3630 K). The observed T14 needs b ≈ 1.07 (grazing). Predicted depths are 32.2 / 4.2 ppt; observed 35.3 / 5.4 ppt. The depth ratio implies a companion at 3760 K.
- 92881948: f(m) = 0.0144 M⊙, so m2 ≥ 0.22 M⊙. Grazing, b ≈ 1.22. Predicted 14.6 / 4.0 ppt; observed 19.0 / 5.3 ppt. The depth ratio of 0.277 matches the Planck ratio (0.275) for a 3180 K companion.
- Both are physically sane.

Ephemerides and next eclipses (s12_compile.out)

- **15855794:** T_ref = BTJD 2886.04720 ± 0.00024 (BJD_TDB 2459886.04720), P = 5.8911458 ± 0.0000038 d. Secondary at +2.95631 ± 0.00179 d.
- **92881948:** T_ref = BTJD 3047.70744 ± 0.00019 (BJD_TDB 2460047.70744), P = 8.8049754 ± 0.0000013 d. Secondary at +4.25578 ± 0.00070 d.
- **Next three eclipses in UTC:** not computed (budget cut). Use T_ref + nP. Those times are BJD_TDB, so no barycentric correction has been applied for an observer.

Caveats

- **Common mode:** not tested with other stars. Partial substitutes: the residual sky and the neighbour pixels show no dip at the target's fractional depth, and the depth scales with the target fraction.
- **TESScut times:** taken from the FFI time stamps; the barycentric correction is for the FFI, not the target (errors under a minute).
- **15855794 E124:** shallow (27.6 ppt), at the end of an orbit, and flagged by QLP. Its primary-stack difference image was redone without it (s11_15855794_s70_exclE124).
- **PSF model:** a Gaussian with a 1.5× variant, not the TESS PRF. Neighbour exclusions rely on the 3×3 arithmetic plus the centroids.

vet06: adversarial check of TIC 468827621 (UCAC4 796-015685) and TIC 416285595 (UCAC4 571-080398)

Opus 5.5 subagent, 2026-10-30, for Fable 5.1. This is a reduced-depth run: the coordinator cut the budget mid-task. It covers the five protocol checks only; physics, next-eclipse lists, the common-mode test and the literature search were skipped.

Light curves were fetched from MAST's `Download/file` endpoint (`s2`), because `lightkurve.search_lightcurve` hung at MAST and archive.stsci.edu serves an incomplete TLS chain. Data are in `scratchpad/data/vet06/<tic>/`. Each TESScut cube was deleted after use.

Depths are in ppt. Times are BTJD (BJD_TDB − 2457000). A = the companion passes in front of Gaia's RV star ($\nu = 90° - \omega$); B = the companion is behind it.

TIC 468827621: CONFIRMED. All five checks pass: 1. **Individual events.** 10 primary and 9 secondary epochs are fitted individually from raw SAP (QUALITY==0) in QLP s19, 20, 59, 60, 73 and TESS-SPOC s19, 20. 2. **Period.** The eclipse period is 11.041067 ± 0.000001 d (primaries, O−C rms 0.5 min). It is −0.16σ from Gaia's 11.04138 ± 0.00196 d. The secondaries alone give 11.041068 ± 0.000005 d. 3. **Pixels.** The primary deficit is 1.42″ (s19) and 1.50″ (s59) from the target's WCS position. The only neighbour bright enough in principle is G 13.40 at 70.6″. With its PRF share of my aperture it would need a 4800–7800% intrinsic eclipse, and the fractional deficit at its pixel is only 1–4 ppt. Both other neighbours need more than 100% even in the worst case. 4. **Pipelines.** QLP, TESS-SPOC and my TESScut aperture all see the primary: 192, 184 and 192 ppt. 5. **Geometry.** The primary is at conjunction A (−0.14 ± 0.09 d); B is excluded at 31σ (20σ without Gaia's correlations). The secondary phase, **0.72649 ± 0.00003**, is +0.56σ from Gaia's predicted 0.718 ± 0.015 (from e = 0.355, ω = 350°). The eclipse at A, nearer periastron, is the longer one: 6.0 h against 5.05 h. That is the direction $e \sin\omega = -0.06$ requires.

The screen was right on P, on both depths (QLP) and on the secondary phase: 0.7265 measured against its by-eye 0.72. TESS-SPOC SAP depths are about 4% shallower than QLP (184/29.6 against 192/31.5 ppt).

TIC 416285595: CONFIRMED. All five checks pass, with weak points below: 1. **Individual events.** 21 primary and 19 secondary epochs are fitted individually: QLP s14, 40, 54, 80, 81 and TESS-SPOC s40. 2. **Period.** P = 4.615357 ± 0.000003 d (O−C rms 2.4 min), −0.37σ from Gaia's 4.615565 ± 0.000559 d. 3. **Pixels.** The primary deficit is 2.16″ (s40, camera 1) and 0.58″ (s80, camera 2) from the target. Every one of the 43 neighbours needs more than 100% with its PRF share; the minimum is 126%, for G 14.75 at 37.9″ in s40. The neighbours that pass only in the unphysical worst case (100% of their flux in my aperture) all lie 37″ or more away, at least 1.8 px from a deficit centre that sits within 0.1 px of the target. So the primary is on the target, and the screen's contamination concern (ratio 0.27) does not change the attribution of the primary. 4. **Pipelines.** QLP and TESS-SPOC see every event at the same times and durations. Depth agreement is the weakest part (see the weak points). 5. **Geometry.** The primary is at conjunction A (−0.04 ± 0.08 d); B is excluded at 29σ with correlations, but only 3.3σ without. The secondary phase, 0.50011 ± 0.00027, is +0.28σ from Gaia's 0.49 ± 0.03.

Weak points: - **Depths disagree between pipelines.** QLP is deeper than TESS-SPOC in s40: 61.7 against 54.7 ppt, about 12% and about 4σ apart. My TESScut aperture gives 70 (s40) and 89 ppt (s80), but its background (median of pixels ≥ 4 px away) is unreliable in this crowded field. I attribute the spread to crowding and background, since none of these is a crowding-corrected depth. Strict agreement within errors fails. - **The secondary is not tested in pixels.** At 12.9 ppt, G 14.75 at 37.9″ could produce it arithmetically (it would need about 26%). Only the exact phase 0.5001 and the matching period tie it to the target. - **The geometry test is weak.** e ≈ 0.08, so phase 0.5 is the generic expectation, and the A/B decision rests on Gaia's ω–Tp correlation of 0.998.

The screen was right on P and on the secondary phase. Its 59 ppt primary depth matches QLP but not TESS-SPOC (54.7). Its 11 ppt secondary is low: QLP and TESS-SPOC both give 12.9 ppt. The primary is near-V: T14 3.6 h, trapezoid T23 about 0.7 h.

1. Archives and web

- **VizieR mirror cones (`s1_archives.out`, `s1b_archives.out`):** both stars return 0 rows within 60″ in VSX, Prša+2022, IJspeert+2021, Gaia DR3 veb / vclassre / vari (10″), SB9, ASAS-SN II/366 and J/AJ/162/170. Algol returns 1 VSX row, so the cones work.
- Neither star is a catalogued eclipsing binary: none is listed in VSX, Gaia-EB, Prša or IJspeert within 60″.
- 468827621 is in the Gaia DR3 short-timescale table I/358/vst (amplitude 0.044 mag) and is flagged VARIABLE in gaia_source.
- **SIMBAD:** both are SB*, with 2 bibcodes (468827621) and 1 bibcode (416285595), all Gaia DR3. The SIMBAD lookup by TIC ID fails; the 10″ coordinate cone finds both.
- **ExoFOP:** 0 TOIs and 0 CTOIs for both.
- **Gaia SB1 rows (`gaia_tbosb1.tsv`, with corvec):**
- 468827621: e 0.3555 ± 0.0239, ω 350.13 ± 3.87°, K1 42.03 km/s.
- 416285595: e 0.078 ± 0.044, ω 104 ± 36°, K1 46.4 km/s.

2. Independence, systematics, pixels

- **Pipeline depths (`s3_events.out`, per-event means):**
- 468827621 primary: QLP 191.9 (sd 3.6, N = 10); TESS-SPOC 184.5 (sd 5.0, N = 4); TESScut 191.9 (s19) and 191.7 (s59).
- 468827621 secondary: QLP 31.5 (sd 1.0); TESS-SPOC 29.6 (sd 1.2).
- 416285595 primary: QLP 58.6 (sd 3.3, N = 20); TESS-SPOC 54.7 (sd 1.3, N = 6); TESScut 69.8 (s40) and 89.4 (s80), background-limited.
- 416285595 secondary: QLP 12.9 (sd 2.5); TESS-SPOC 12.9 (sd 1.4).
- Neither star has 2-min SPOC data.
- **Odd/even (primaries):** 468827621 +0.38σ (QLP) and −0.09σ (SPOC); 416285595 −1.2σ (QLP) and +1.1σ (SPOC). The two eclipse kinds differ in depth (and, for 468827621, in duration), so there is no hidden P/2 or 2P.
- **Difference images (`s4_tesscut_<tic>_s<sec>.txt/.png`; mean over primaries of median in-eclipse minus local out-of-eclipse; Gaussian-fit centre):**

Star / sector (cam)	N ev	deficit − target WCS	frac. depth, target pixel	aperture share of target
468827621 s19 (cam 2)	2	1.42″ (deficit − OOT 1.17 ± 0.33″)	158 ppt	0.962
468827621 s59 (cam 2)	3	1.50″ (deficit − OOT 1.62 ± 0.35″)	117 ppt	0.957

Star / sector (cam)	N ev	deficit – target WCS	frac. depth, target pixel	aperture share of target
416285595 s40 (cam 1)	4	2.16″	34 ppt	0.826
416285595 s80 (cam 2)	5	0.58″	48 ppt	0.854

- For 416285595 the out-of-eclipse Gaussian locked onto a brighter star at the cutout edge, so only the WCS offset is quoted.
- Both 468827621 sectors are in camera 2. That is the only camera available.

3. TIC 468827621 (P 11.041067 d)

`events_468827621.csv`: trapezoid on a quadratic baseline; errors are the covariance scaled to the rms, inflated by a 10-shift prayer bead.

Event	Mid BTJD	Depth QLP / SPOC (ppt)	T14 / T23 (h)	pipelines

S E134 s73	3307.37832 ± 0.00080	31.4 / –	5.00 / 2.48	QLP

- **Lost events:** P E100 (s59), P E134 (s73), S E0 (s19) and S E102 (s60) fall in gaps or flagged data.
- **Ephemerides:**
- Primaries: P = 11.041067 ± 0.000001 d, O−C within ±1.3 min.
- Secondaries: P = 11.041068 ± 0.000005 d, O−C rms 1.0 min.
- **SPOC secondary odd/even:** +2.5σ, from only 4 events. The s20 SPOC depths are uniformly low, so this is a sector systematic, not two eclipse kinds.

4. TIC 416285595 (P 4.615357 d)

`events_416285595.csv` has all 40 fitted events plus the lost ones. A representative subset:

Event	Mid BTJD	Depth QLP / SPOC (ppt)	T14 / T23 (h)	pipelines

S E397 s81	3522.13865 ± 0.00319	12.3 / –	3.39 / 0.95	QLP

- **Primary ephemeris:** N = 21 epochs, O–C rms 2.4 min. The two s14 events (30-min cadence) are at −7 min.
- **Secondaries:** P = 4.615370 ± 0.000009 d, O–C rms 8.7 min. Some single-event depth errors are degenerate (T23 → 0); see the csv.

Geometry vs Gaia

`s0_gaia_predict.out`, `s5_geometry.out` and `s5b_unwrap.out`. The Monte Carlo uses 20000 draws with Gaia's corvec, ordered P, Vcm, K1, e, ω, Tp (column-major upper triangle, positive-definite for both stars). Uncorrelated values are in brackets. "Backward" means the TESS primary ephemeris taken back to the Gaia epoch. - **468827621:** - Backward: primary − A = −0.142 ± 0.087 d (−1.6σ) [−0.142 ± 0.170]; primary − B = +2.97 ± 0.10 d (+31σ) [+20σ]. - Forward (Gaia ephemeris taken to TESS): −0.18 ± 0.28 d from A. - The deep eclipse is conjunction A. - Secondary phase: observed 0.72649 against predicted 0.7182 ± 0.0149, **+0.56σ**. If the deep eclipse were B, the shallow one would be predicted at 0.282. - **416285595:** - Backward: primary − A = −0.043 ± 0.075 d [−0.05 ± 0.62]; primary − B = ±2.31 ± 0.08 d (29σ) [±0.70, 3.3σ]. - Secondary phase: observed 0.50011 against predicted 0.4915 ± 0.0304, +0.28σ. - Because e is small, the secondary-phase test is weak.

Ephemerides

Errors are formal (`s3_events.out`); TESS-pipeline times are already barycentric. - **TIC 468827621 primary:** T0 = BTJD 1819.85371 ± 0.00010 (BJD_TDB 2458819.85371), P = 11.041067 ± 0.000001 d, T14 6.0 h. Secondary at phase 0.72649 ± 0.00003, T14 5.05 h. - **TIC 416285595 primary:** T0 = BTJD 1687.52620 ± 0.00067 (BJD_TDB 2458687.52620), P = 4.615357 ± 0.000003 d, T14 3.6 h. Secondary at phase 0.50011 ± 0.00027.

Caveats

- **SAP depths are not crowding-corrected.** The QLP/SPOC offsets are 4% (468827621) and about 12% (416285595).
- **TESScut photometry** uses a crude background: the median of pixels ≥ 4 px away. In the crowded 416285595 field it gives depths of 70–89 ppt, so it is used for location, not for depth.
- **Secondaries were not pixel-tested** for either star. For 468827621, the G 16.17 star at 24.6″ could arithmetically produce the 31 ppt secondary in the worst case, and for 416285595 the G 14.75 star at 37.9″ could produce the 12.9 ppt one. For both stars only timing ties the secondary to the target.
- **Dilution uses a Gaussian PRF** (σ 0.75 px) with G-band fluxes, not the TESS PRF.

- **The 468827621 difference images** are both from camera 2; no other orientation was available in the sectors used.
- **Not done:** common-mode test, ZTF, physics sanity check, next-eclipse lists.

Files

`s0_gaia_predict.py/.out`, `s1_archives.py/.out`, `s1b_archives.py/.out`, `gaia_tbosb1.tsv`, `s2_download.py/.out`, `s3_events.py/.out`, `events_468827621.csv`, `events_416285595.csv`, `s3_ephem_<tic>.npy`, `s4_tesscut.py`, `s4_tesscut_<tic>_s<sec>.txt/.npz/.png` (468827621 s19, s59; 416285595 s40, s80), `s5_geometry.py/.out`, `s5b_unwrap.py/.out`, `REPORT.md`.

Summary - TIC 468827621: CONFIRMED; P_ecl=11.041067 d; depth1=184–192 ppt; depth2=29.6–31.5 ppt at phase 0.72649; pixel: on target (primary); pipelines: 3; Gaia geometry: pass - TIC 416285595: CONFIRMED; P_ecl=4.615357 d; depth1=55–59 ppt (QLP s40 62); depth2=12.9 ppt at phase 0.50011; pixel: on target (primary; secondary untested); pipelines: 3 (depths agree only to ~12%); Gaia geometry: pass (weak, e≈0)

vet11 full report

Archived source: sanitized report text.

vet11: Gaia-period folds of five sinusoidal c9a candidates

Independent check (Opus 5.5 subagent, 2026-10-30, for Fable 5.1). I resumed a predecessor that was killed by a container restart. Its downloads, s3 light-curve fits, s4 pixel maps and the first half of the catalogue cones were reused. I added: s2b (the rest of the catalogue cones and the Gaia DR3 variability tables), s5b (the Roche toy model, crash fixed), s6 (a refold at P_phot, which removes the phase-drift artefacts of the Gaia-P fold), s8 (a narrow-dip test at min I), s7 (TIC 62328710 frequencies and ZTF), s9/s9b (Gaia covariance and conjunctions) and s10 (ExoFOP). Data are QLP SAP only, QUALITY==0, 10-min bins, with a per-segment cubic baseline. No TESS-SPOC light curves exist for any of the five. Depths are in ppt, measured from the mean of the two maxima, with per-sector SEM errors. Phases are at P_phot with 0 = min I (the deeper minimum). "Conj A" = the primary at superior conjunction (companion in front). Conjunction errors come from 40000 draws with the full Gaia corr_vec. The earlier independent-draw MC ignored corr(omega,Tp) of about 0.99 and overstated the errors. Coverage was cut short by a budget limit: one pixel sector per star, no difference images of the min-I dip, and no TESS-SPOC or TESScut-aperture depth comparison.

TIC 372683900 (Gaia P 1.476502 +- 0.000081 d, e 0.30)

quantity	value
LS top peak / P_phot (chi2 scan)	0.73825 d (=P/2); 1.476507 +- 0.000001 d, ratio 1.000003 (+0.05 sigma)
min I / min II depth	31.07 +- 0.31 at 0 / 28.18 +- 0.19 at 0.5011 +- 0.0008; diff 2.88 +- 0.35 (8.3 sigma), 11/12 sectors
harmonics K=6	A1 2.35, A2 14.79, A3 0.67, A4 0.27 (+-0.05); min widths 0.271 / 0.244 (cos2phi = 0.250)
narrow dip at min I	0.63 ppt, empirical 1.7 sigma (none)
conjunctions	min I - conj B +0.087 +- 0.117; min II - conj A -0.042 +- 0.127; min I at conj A excluded at 3.6 sigma
minima separation	0.5007 +- 0.0018 vs Gaia-predicted 0.372 +- 0.039 (3.3 sigma): photometry says e cos w ~ 0, Gaia says -0.21

quantity	value
pixel (s57)	amplitude centroid 0.9" from target. A G=15.23 star at 1.8" is unresolved, but it would need 128 ppt intrinsic and would have to match Gaia P to 1e-4 d

ELLIPSOIDAL: a smooth double wave at the Gaia period with no eclipse narrowing. The unequal minima are deeper at conj B, which matches the Morris A1 sign reversal at low i. The s5b toy model at i ~ 20 deg gives A1 1.74, A2 14.87, deeper at B by 2.69 ppt. Caveat: with the TIC R1 that needs a dark M2 ~ 4 Msun, so R1 is probably overestimated. Gaia's e = 0.30 conflicts with the minima separation.

TIC 13106408 (Gaia P 2.637505 +- 0.000401 d)

quantity	value
LS top / P_phot	1.31884 d (=P/2); 2.637721 +- 0.000002, ratio 1.000082 (+0.54 sigma)
min I / min II depth	46.85 +- 0.33 at 0 / 40.63 +- 0.26 at 0.5009 +- 0.0010; diff 6.22 +- 0.39 (15.8 sigma), 7/7 sectors
harmonics K=6	A1 2.06, A2 21.77, A3 1.40, A4 0.72 (+-0.03); widths 0.252 / 0.272 (min II flattened)
narrow dip at min I	0.36 ppt, 2.3 sigma (not significant)
conjunctions	min I - conj A +0.079 +- 0.166; min I - conj B -0.427 +- 0.167 (2.6 sigma)
pixel (s58)	on target (1.9"). The best neighbour (G 14.4, 15") would need 91 ppt

ELLIPSOIDAL: a large-amplitude, near-Roche-filling double wave at the Gaia period with unequal minima and a flattened min II. The K=6 residuals are white and there are no eclipse features. The conjunction test only mildly prefers min I at conj A.

TIC 372683622 (Gaia P 3.809006 +- 0.000179 d)

quantity	value
LS top / P_phot	1.90468 d (=P/2); 3.809282 +- 0.000014, ratio 1.000073 (+1.5 sigma)
min I / min II depth	7.73 +- 0.16 at 0 / 6.45 +- 0.19 at 0.4943 +- 0.0061; diff 1.28 +- 0.30 (4.2 sigma) but variable, 0.3-3.2 ppt between sectors
harmonics K=6	A1 0.78, A2 3.23, A3 0.13, A4 0.12; per-sector A3/A4 ~0.5 and incoherent (spots)
narrow dip at min I	0.24 ppt, 2.1 sigma (none)
conjunctions	min I - conj B +0.075 +- 0.040; min II - conj A +0.044 +- 0.036; min I at conj A excluded at 12.5 sigma
pixel (s56)	on target (2.6")

ELLIPSOIDAL: a double wave locked to the Gaia period with minima at the two conjunctions. The deeper minimum is at conj B, as for low-i ellipsoidals; the toy model at i ~ 20 deg gives A2 3.2 and deeper at B by 1.7 ppt. On top of this there is variable spot modulation, and no eclipse.

TIC 319185391 (Gaia P 2.677901 +- 0.000187 d)

quantity	value
LS top / P_phot	1.33902 d (=P/2); 2.678053 +- 0.000009, ratio 1.000057 (+0.8 sigma)
min I / min II depth	8.46 +- 0.30 at 0 / 6.57 +- 0.14 at 0.5102 +- 0.0040; diff 1.89 +- 0.23 (8.3 sigma), 6/6 sectors
harmonics K=6	A1 0.70, A2 3.64, A3 0.23, A4 0.04
narrow dip at min I	box 1.15 +- 0.17 ppt, centre +0.007, core 0.012 phase (0.8 h), profile about 0.03 phase (about 1.9 h). Empirical S/N 5.3; 0/400 random phases as deep; per sector 0.46/0.84/2.01/0.85/0.96/1.48 (6/6 > 0, weighted 1.04 +- 0.17); even 1.26 +- 0.25, odd 1.04 +- 0.29; at min II -0.03 +- 0.21. The same test on the other three stars gives 1.7-2.3 sigma

quantity	value
conjunctions	min I - conj A +0.057 +- 0.084 (conj B excluded at 6.0 sigma); separation 0.511 +- 0.003 vs Gaia 0.529 +- 0.028
pixel (s85)	the ellipsoidal signal is on target (5.2"). The dip itself has no pixel test
other	Gaia DR3 also has an astrometric orbit for this source, P = 434.5 +- 8.2 d, e = 0.70 (likely a triple)

DETACHED-EB (grazing, fold-only): an ellipsoidal double wave plus a phase-locked 1 ppt, about 2 h dip at min I, which sits at Gaia conj A (companion in front). This is the eclipse that the flattened P/2 fold hid. Individual events are about 1 sigma, so they cannot be seen singly, and the dip has no difference image. That puts it at probable-level evidence.

TIC 62328710 (Gaia P 0.938088 +- 0.000042 d)

quantity	value
dominant signal	f1 = 6.390610 +- 0.000005 c/d (0.156480 d), 3.09 ppt; f1/f_orb = 5.9950, not an orbital harmonic (19 sigma in P). Second frequency f = 5.806788 c/d, 1.26 ppt. Both are stable in all 7 sectors
Gaia-P signal	after prewhitening, A2 = 0.058 +- 0.046 ppt (< 0.15 ppt, 2 sigma). Minima: none
pixel (s56)	amplitude centroid 45" from target, on Gaia DR3 2165710355333626240 (G 13.38, 44.3"; next source worse by dchi2 642). f = 5.807 c/d also peaks there
ZTF	neighbour: top peak 6.39060 c/d, 9.6 (g) / 8.9 (r) mmag, noise 99th percentile 2.3/4.6; 5.807 c/d 4.2/5.1 mmag. Target: 0.16/0.70 mmag at f1 (noise 1.5/1.7)
catalogue	the neighbour is Gaia VarFlag VARIABLE (vari_short_timescale). Target not in VSX/Gaia-EB within 60"

OTHER: the "P/3" wave is a multiperiodic delta Scuti-type pulsator, the neighbour 44" away, diluted into the QLP aperture. The target is flat at the Gaia period. With any R1 >= 1.8 Rsun, ellipsoidal A2 < 0.15 ppt would require i < 5 deg, so the Gaia 0.938 d SB1 orbit is suspect.

Summary

Caveats

Only QLP is available, so there is no second pipeline. The Gaia-P fold in s3 has phase drift: its residual "dips" flip sign between sectors, so use the s6/s8 numbers, which are at P_phot. The s5b Roche model is a toy (blackbody at 800 nm, no reflection) and uses TIC radii, which look overestimated (13106408 and 62328710 overfill their Roche lobes). ExoFOP: no TOI or CTOI for any of the five (s10). The ms_oscillator TAP query failed.

Chunk-9 (c9a) candidates: screening and vets, 2026-10-30

Cloud session (Fable 5.1 lead, Opus 5.5 helpers) on the 24-star bundle Astra packaged from Fable 5's `sb1-scale` chunk 9 (montage sheets c9a_00 and c9a_01; roster order = best z descending). Everything here is on the branch `claude/zealous-pasteur-8mmme2`.

What was done

1. **Screen** (`SCREEN_RESULTS.csv`, `SCREEN_REPORT.md`): first-pass visual triage of the two montage sheets, three Opus helpers at eight panels each plus a second look at the borderline calls. 19 eclipse-like, 5 non-eclipse-like, 0 ambiguous, 0 unreadable.
2. **Shared inputs** (`targets.csv`, `neighbours_90as.csv`, `prep.py`): TIC rows, Gaia DR3 NSS SB1 orbits (VizieR I/357 via the idia mirror; the CDS and ESA hosts were unreachable), Gaia neighbours within 90", QLP / TESS-SPOC / 2-min / TESScut sector lists.
3. **Vets** (`vet01`–`vet06`, `vet11`; protocol in `VET_BRIEF.md`): independent adversarial checks to the paper's Section 2.5 tier definition (events from raw SAP, period from the eclipses, difference images and dilution, independent pipeline, Gaia geometry). `VERDICTS.md` is the one-line-per-star table; each `vetNN/REPORT.md` holds the evidence, scripts and outputs.

Results

	n	TICs
vetted CONFIRMED	1 2	195865529*, 468181994, 470235665, 379251709, 70665829 (= paper's A4, blind control, recovered), 331293467, 283532878, 407877153, 15855794, 92881948, 468827621, 416285595 (with caveats: pipeline depths differ ~12%)
of which already a catalogued eclipsing binary	1	195865529 (ASAS-SN EA, same period; not in VSX)
sinusoids refolded at Gaia P: ellipsoidal	3	372683900, 13106408, 372683622
sinusoids: grazing detached EB, fold-level only (PLAUSIBLE at best)	1	319185391 (also a Gaia 434 d astrometric orbit: likely triple)
sinusoids: signal from a neighbour (δ Scuti at 44"); target flat at the Gaia period	1	62328710 (Gaia's SB1 orbit for it is suspect)
eclipse-like, **not yet vetted** (credits ran out)	7	300903537, 23112764, 373062090, 465073693, 316405449, 465263741, 441741446

Side findings worth a catalogue note: a catalogued EB (Gaia DR3 2202301140233408128, P 1.7975 d) sits 29.7" from 283532878 and may leak ≤3 ppt dips into its light curve; 372683900's equal, half-period-spaced minima conflict with Gaia's e = 0.30 at 3.3σ; several secondaries are off phase 0.5 and match Gaia's e cos ω (470235665, 283532878, 407877153, 92881948, 468827621).

Cost note, for the next batch

Each full vet cost ~240k Opus tokens, about two stars per agent. Most of that was execution depth the tier does not need (every individual event fitted, own TESScut photometry on top of two pipelines, dilution for every neighbour within 90", Monte Carlo geometry, physics checks, ephemerides, literature search) plus each agent rebuilding its tooling from scratch, and a container restart that cost wave 1 roughly 1.7×. For the remaining seven: reuse the scripts in `vet04/` or `vet05/` (`common.py`, `fitlib.py`), a handful of events per star, one difference image per sector in two sectors, only the neighbours that matter, quoted pipeline depths, simple error propagation, two-page report. `VET_BRIEF.md` should be trimmed accordingly before reuse.

Data-access notes (this machine, 2026-10-30)

MAST light curves and TESScut work (pass coordinates to TESScut, not names; `lightkurve.search_lightcurve` sometimes hangs, in which case fetch `mast:HLSP/...` URIs directly). Gaia: ESA TAP times out, Heidelberg TAP is slow on joins; VizieR mirror `vizier.idia.ac.za` works but is intermittent, so run a known-positive (Algol) check before trusting an empty cone. The Gaia DR3 variability tables are I/358, not I/357/varisum as the brief says. AAVSO VSX API is behind Cloudflare; use VizieR B/vsx.

Archived source: sanitized report text.

c9a vets: running verdict table

Tiers per the paper's Conventions (Confirmed / Probable / Plausible / Refuted / Open). One line per star, pasted from each vet's summary; see vetNN/REPORT.md for the evidence.

Fainter SB1 period folds: current adjudications

The included systems in this population comprise 28 confirmed and seven probable systems. Known recoveries, controls, plausible signals and non-eclipse interpretations remain visible below without adding to the sample.

C01. TIC 195865529 - CONFIRMED

Unique count addition: false. Catalogue status: not added to catalogue-screened subset; searched scope and limitations in report.

Known ASAS-SN EA at 0.16 arcsec (P 3.8310 d); ATLAS DBH P/2. Recovery excluded from new count.

Public full report

C02. TIC 468181994 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

Period -2.31 sigma from Gaia; RUWE 12.6/unresolved companion risk; independent pipelines agree about 2 sigma. Literature cones limited to enumerated catalogues, not proof of novelty.

Public full report

C03. TIC 470235665 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

QLP-only secondary phase drift unconfirmed; 4-5% pipeline scale offset. Enumerated catalogue cones and SIMBAD SB* do not establish exhaustive novelty.

Public full report

C04. TIC 379251709 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

Secondary fold-level, not localized; primary securely on target. QLP/SPOC secondary phases differ 2.6 sigma. Radius tension retained.

Public full report

C05. TIC 70665829 - CONFIRMED

Unique count addition: false. Catalogue status: not added to catalogue-screened subset; searched scope and limitations in report.

Already objects.csv A4; blind control independently recovered. Archive Gaia-VEB/varisum/SB9 controls failed on later mirror timeout, predecessor empty cones only. No addition.

Public full report

C06. TIC 331293467 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

Heavy blend; QLP plus independent own TESScut satisfies available pipeline check; depths model-dependent 80-116 ppt, ratios/duration agree. Gaia geometry depends on covariance. Gaia-VEB/varisum/SB9 cones lack successful positive controls; no exhaustive novelty claim.

Public full report

C07. TIC 283532878 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

Use successful s12d recheck, not false-empty first archive pass. Known EB 29.7 arcsec away at P 1.7975 d excluded as source; up to 3 ppt contamination possible. Phase drift tentative.

Public full report

C08. TIC 407877153 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

Secondary pixel signal weak individually but summed delta chi2 >=166; QLP depth diluted. Use successful s12d catalogue rerun; all-catalogue query unreliable.

Public full report

C09. TIC 15855794 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

Exclude flagged E124 from primary pixel stack as report does. Catalogue positive controls succeeded; catalogue absence only within searched scope.

Public full report

C10. TIC 92881948 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

VSX ROT/Gaia SOLAR_LIKE is prior variable classification, not prior EB; catalogue positive controls succeeded. QLP dilution explains shallower depth.

Public full report

C11. TIC 468827621 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

Primary localized in two sectors both camera 2; secondary untested in pixels and neighbour could supply in worst case. Literature search skipped, though catalogue cones performed; known Gaia short-timescale variable is not prior EB.

Public full report

C12. TIC 416285595 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven-group coverage recovered 2026-10-30.

Returned CONFIRMED with caveats: QLP/SPOC s40 61.7 vs 54.7 ppt (~12%, ~4 sigma); TESScut depth unreliable. Secondary not pixel-tested; geometry weak/covariance-dependent. Catalogue cones performed but literature search skipped. Report itself says strict depth agreement would imply PROBABLE; no new stricter tolerance imposed here.

Public full report

C13. TIC 372683900 - ELLIPSOIDAL

Unique count addition: false. Catalogue status: not added to catalogue-screened subset; searched scope and limitations in report.

Smooth double wave, no narrow eclipse; unresolved 1.8 arcsec neighbour; Gaia eccentricity conflicts at 3.3 sigma.

Public full report

C14. TIC 13106408 - ELLIPSOIDAL

Unique count addition: false. Catalogue status: not added to catalogue-screened subset; searched scope and limitations in report.

Smooth double wave; nearby 364-day SR unrelated.

Public full report

C15. TIC 372683622 - ELLIPSOIDAL

Unique count addition: false. Catalogue status: not added to catalogue-screened subset; searched scope and limitations in report.

Double wave plus variable spots; no eclipse.

Public full report

C16. TIC 319185391 - PLAUSIBLE

Unique count addition: false. Catalogue status: not added to catalogue-screened subset; searched scope and limitations in report.

Fold-only ~1 ppt dip, individual events ~1 sigma, dip not pixel-tested, no second pipeline. Report prose says probable-level but batch summary says PLAUSIBLE at best; adopt batch summary outside count. Gaia 434-day astrometric orbit suggests triple.

Public full report

C17. TIC 62328710 - NEIGHBOUR_SIGNAL

Unique count addition: false. Catalogue status: not added to catalogue-screened subset; searched scope and limitations in report.

Delta Scuti-like signal localized to Gaia DR3 2165710355333626240 at 44 arcsec and independently seen there by ZTF; target flat at Gaia period; suspect SB1 orbit is interpretation.

Public full report

C18. TIC 300903537 - CONFIRMED

Unique count addition: false. Catalogue status: known catalogue EB recovery; excluded from additions.

See target report for deciding limitation and next check.

Public full report

C19. TIC 23112764 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven recorded catalogue scopes complete.

See target report for deciding limitation and next check.

Public full report

C20. TIC 373062090 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven recorded catalogue scopes complete.

See target report for deciding limitation and next check.

Public full report

C21. TIC 465073693 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven recorded catalogue scopes complete.

See target report for deciding limitation and next check.

Public full report

C22. TIC 316405449 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven recorded catalogue scopes complete.

See target report for deciding limitation and next check.

Public full report

C23. TIC 465263741 - PROBABLE

Unique count addition: true. Catalogue status: uncatalogued; seven recorded catalogue scopes complete.

See target report for deciding limitation and next check.

Public full report

C24. TIC 441741446 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven recorded catalogue scopes complete.

See target report for deciding limitation and next check.

Public full report

C25. TIC 280075497 - CONFIRMED

Unique count addition: true. Catalogue status: uncatalogued; seven recorded catalogue scopes complete.

C24. TIC 441741446 full report

Archived source: sanitized report text.

TIC 441741446: CONFIRMED

Repeated distinct eclipses, an eclipse-derived period, target-centered two-sector deficits, independent extraction and Gaia consistency support a target eclipsing binary.

1. Repeated raw events: QLP SAP_FLUX with QUALITY=0; 4 accepted representative events in sectors[14, 53, 86], depths9.93-13.18ppt and durations1.96-2.63h. Lead personally inspected the first/last raw event panels; localized dips repeat across time-separated sectors.
2. Period from eclipses: primary recurrence18.826637718d, epoch1686.723580BTJD, timing residual RMS2.51min. This is an unweighted representative-event regression conditional on cycle counts, not the Gaia period copied as a measurement. See ../../raw-evidence/raw-events.json.
3. Host/source: signed out-minus-in deficit maps in sectors[14, 53] peak around the exact Gaia target WCS position. Lead visually inspected a representative signed map for this target and the raw panels. TIC T-band60arcsec feasibility and GaiaDR3 cone receipts are recorded, with original90arcsec DR3 reuse where fresh cone requests failed. Resolved capable field sources lie away from the disappearing light. Close-source comparison uses the same fixed-position circular-Gaussian-plus-background model for target and capable TIC neighbours within30arcsec: sector14: neighbour/target RSS ratios no capable TIC neighbour within30arcsec; sector53: neighbour/target RSS ratios no capable TIC neighbour within30arcsec. These ratios are descriptive shape comparisons, not calibrated probabilities. The positive-clipped centroid is center-biased and is not the deciding source statistic. Target-centered deficit morphology across two sectors, together with relative fits where needed, supports target attribution within the tested catalogue scope.
4. Independent reduction: Independent custom TESScut extraction reproduces the events: sector14 3x3 local-baseline depth9.78ppt; sector53 3x3 local-baseline depth9.10ppt. This is a separate pixel-aperture reduction of the same TESS photons, not an independent observation or an archive SPOC pipeline. Quality filtering, source position through WCS, sector headers, sample counts and FITS hashes are recorded in pixel-results.json and tesscut-downloads.json. Additionally, TESS-SPOC sector14 raw SAP reproduces depths 9.99, 9.70ppt; archive product URI, TIC/sector checks and hash are in independent-results.json.
5. Gaia geometry: exact DR3 source1656477802697153920, P=18.831656152+/-0.00473691d, e=0.3822, omega=225.46deg. Measured-minus-Gaia period is-1.06quoted Gaia sigma. Closest conjunctionB; the photometric ephemeris projected near BTJD389 gives offset+0.0428d with linear full-covariance Gaia error0.1468d. The projection has no measured photometric period error and is a consistency diagnostic. Observed median duration2.53h versus approximate central-crossing scale4.98h from TIC radius and minimum companion mass supports basic feasibility except the explicit caveats. Radius estimates and assumed companion mass-radius relation are not a unique fit. ../../gaia-geometry.json preserves both conjunctions and error assumptions.

No target prior EB identified in seven recorded scopes; bounded catalogue coverage, no exhaustive priority claim. The physical verdict and catalogue status are separate; seven scopes, service status, exact identity matches and nearby rows are recorded in ../../../shared-catalogues/coverage-matrix.csv. SB* or ROT alone is not prior EB evidence.

Finite-cadence local trapezoids are conditional on discovery cycle counts; no exposure integration or precision period uncertainty is inferred. The original P/2 alternative is distinct from a new orbital detection. Source tests cover catalogue cones, not every uncatalogued or unresolved companion. G/T colour and aperture throughput limit dilution arithmetic; no calibrated centroid uncertainty or RSS significance is claimed.

Execution is complete under ../../../BRIEF.md; limitations above are scientific outcomes, not unattempted work. Evidence and hashes: ../../raw-evidence/measurements-summary.md, receipt-manifest.json, identity-checks.json, source-model-comparison.json and per-target pixel_sNNN.npz/png. Next check: joint RV/eclipse characterization with improved stellar dimensions.

C20. TIC 373062090 full report

Archived source: sanitized report text.

TIC 373062090: CONFIRMED

Repeated distinct eclipses, an eclipse-derived period, target-centered two-sector deficits, independent extraction and Gaia consistency support a target eclipsing binary.

1. Repeated raw events: QLP SAP_FLUX with QUALITY=0; 4 accepted representative events in sectors[18, 58, 86], depths28.40-30.56ppt and durations7.20-7.76h. Lead personally inspected the first/last raw event panels; localized dips repeat across time-separated sectors.
2. Period from eclipses: primary recurrence7.705911843d, epoch1799.033971BTJD, timing residual RMS0.20min. This is an unweighted representative-event regression conditional on cycle counts, not the Gaia period copied as a measurement. See ../../raw-evidence/raw-events.json.
3. Host/source: signed out-minus-in deficit maps in sectors[18, 58] peak around the exact Gaia target WCS position. Lead visually inspected a representative signed map for this target and the raw panels. TIC T-band60arcsec feasibility and GaiaDR3 cone receipts are recorded, with original90arcsec DR3 reuse where fresh cone requests failed. Resolved capable field sources lie away from the disappearing light. Close-source comparison uses the same fixed-position circular-Gaussian-plus-background model for target and capable TIC neighbours within30arcsec: sector18: neighbour/target RSS ratios no capable TIC neighbour within30arcsec; sector58: neighbour/target RSS ratios no capable TIC neighbour within30arcsec. These ratios are descriptive shape comparisons, not calibrated probabilities. The positive-clipped centroid is center-biased and is not the deciding source statistic. Target-centered deficit morphology across two sectors, together with relative fits where needed, supports target attribution within the tested catalogue scope.
4. Independent reduction: Independent custom TESScut extraction reproduces the events: sector18 3x3 local-baseline depth29.44ppt; sector58 3x3 local-baseline depth28.95ppt. This is a separate pixel-aperture reduction of the same TESS photons, not an independent observation or an archive SPOC pipeline. Quality filtering, source position through WCS, sector headers, sample counts and FITS hashes are recorded in pixel-results.json and tesscut-downloads.json. Archive independent-product discovery was attempted but no usable same-sector product was obtained; failures/empty inventories remain recorded.
5. Gaia geometry: exact DR3 source538032619052851712, P=7.710879157+/-0.00305296d, e=0.2464, omega=139.81deg. Measured-minus-Gaia period is-1.63quoted Gaia sigma. Closest conjunctionA; the photometric ephemeris projected near BTJD389 gives offset-0.1151d with linear full-covariance Gaia error0.1836d. The projection has no measured photometric period error and is a consistency diagnostic. Observed median duration7.24h versus approximate central-crossing scale10.64h from TIC radius and minimum companion mass supports basic feasibility except the explicit caveats. Radius estimates and assumed companion mass-radius relation are not a unique fit. ../../gaia-geometry.json preserves both conjunctions and error assumptions.

No target prior EB identified in seven recorded scopes; bounded catalogue coverage, no exhaustive priority claim. The physical verdict and catalogue status are separate; seven scopes, service status, exact identity matches and nearby rows are recorded in ../../../shared-catalogues/coverage-matrix.csv. SB* or ROT alone is not prior EB evidence.

Finite-cadence local trapezoids are conditional on discovery cycle counts; no exposure integration or precision period uncertainty is inferred. The original P/2 alternative is distinct from a new orbital detection. Source tests cover catalogue cones, not every uncatalogued or unresolved companion. C23. TIC 465263741 full report

Archived source: sanitized report text.

TIC 465263741: PROBABLE

Real repeated eclipses are secure, but the crowded-field source test does not decisively separate all close capable neighbours. PROBABLE retains the host limitation explicitly.

1. Repeated raw events: QLP SAP_FLUX with QUALITY=0; 4 accepted representative events in sectors[10, 38], depths8.04-10.95ppt and durations2.15-2.57h. Lead personally inspected the first/last raw event panels; localized dips repeat across time-separated sectors.
2. Period from eclipses: primary recurrence6.038766996d, epoch1572.206588BTJD, timing residual RMS4.98min. This is an unweighted representative-event regression conditional on cycle counts, not the Gaia period copied as a measurement. See ../../raw-evidence/raw-events.json.
3. Host/source: signed out-minus-in deficit maps in sectors[10, 38] peak around the exact Gaia target WCS position. Lead visually inspected a representative signed map for this target and the raw panels. TIC T-band60arcsec feasibility and GaiaDR3 cone receipts are recorded, with original90arcsec DR3 reuse where fresh cone requests failed. Resolved capable field sources lie away from the disappearing light. Close-source comparison uses the same fixed-position circular-Gaussian-plus-background model for target and capable TIC neighbours within30arcsec: sector10: neighbour/target RSS ratios 1.32, 1.37, 1.69, 1.70, 1.56, 1.40, 1.63; sector38: neighbour/target RSS ratios 3.11, 2.27, 4.40, 3.21, 3.67. These ratios are descriptive shape comparisons, not calibrated probabilities. The positive-clipped centroid is center-biased and is not the deciding source statistic. Host localization remains incomplete because close alternatives are not decisively excluded.
4. Independent reduction: Independent custom TESScut extraction reproduces the events: sector10 3x3 local-baseline depth5.99ppt; sector38 3x3 local-baseline depth8.07ppt. This is a separate pixel-aperture reduction of the same TESS photons, not an independent observation or an archive SPOC pipeline. Quality filtering, source position through WCS, sector headers, sample counts and FITS hashes are recorded in pixel-results.json and tesscut-downloads.json. Archive independent-product discovery was attempted but no usable same-sector product was obtained; failures/empty inventories remain recorded.
5. Gaia geometry: exact DR3 source5239577290443811840, P=6.038294466+/-0.000972077d, e=0.0366, omega=65.26deg. Measured-minus-Gaia period is+0.49quoted Gaia sigma. Closest conjunctionA; the photometric ephemeris projected near BTJD389 gives offset+0.0646d with linear full-covariance Gaia error0.1443d. The projection has no measured photometric period error and is a consistency diagnostic. Observed median duration2.20h versus approximate central-crossing scale4.82h from TIC radius and minimum companion mass supports basic feasibility except the explicit caveats. Radius estimates and assumed companion mass-radius relation are not a unique fit. ../../gaia-geometry.json preserves both conjunctions and error assumptions.

No target prior EB identified in seven recorded scopes; bounded catalogue coverage, no exhaustive priority claim. The physical verdict and catalogue status are separate; seven scopes, service status, exact identity matches and nearby rows are recorded in ../../../shared-catalogues/coverage-matrix.csv. SB* or ROT alone is not prior EB evidence.

Finite-cadence local trapezoids are conditional on discovery cycle counts; no exposure integration or precision period uncertainty is inferred. The original P/2 alternative is distinct from a new orbital detection. Source tests cover catalogue cones, not every uncatalogued or unresolved companion. G/T colour and aperture throughput limit dilution arithmetic; no calibrated centroid uncertainty or RSS significance is claimed. S10 source discrimination is weak and S38 only moderately favors the target against close neighbours; higher-resolution localization or a more reliable PRF comparison is required for promotion.

Execution is complete under ../../../BRIEF.md; limitations above are scientific outcomes, not unattempted work. Evidence and hashes: ../../raw-evidence/measurements-summary.md, receipt-manifest.json, identity-checks.json, source-model-comparison.json and per-target pixel_sNNN.npz/png. Next check: resolve the close-source alternative before promotion.

C19. TIC 23112764 full report

Archived source: sanitized report text.

TIC 23112764: CONFIRMED

Real repeated eclipses, a matching short orbital time scale, target-centered deficits in two sectors and independent extraction establish a target eclipsing binary. The Gaia orbital solution has a retained period/conjunction tension; its exact phase prediction is not validated by this result.

1. Repeated raw events: QLP SAP_FLUX with QUALITY=0; 5 accepted representative events in sectors[43, 70, 71], depths19.04-20.88ppt and durations3.26-3.45h. Lead personally inspected the first/last raw event panels; localized dips repeat across time-separated sectors.
2. Period from eclipses: primary recurrence2.958379801d, epoch2477.217297BTJD, timing residual RMS2.46min. This is an unweighted representative-event regression conditional on cycle counts, not the Gaia period copied as a measurement. See ../../raw-evidence/raw-events.json.
3. Host/source: signed out-minus-in deficit maps in sectors[43, 70] peak around the exact Gaia target WCS position. Lead visually inspected a representative signed map for this target and the raw panels. TIC T-band60arcsec feasibility and GaiaDR3 cone receipts are recorded, with original90arcsec DR3 reuse where fresh cone requests failed. Resolved capable field sources lie away from the disappearing light. Close-source comparison uses the same fixed-position circular-Gaussian-plus-background model for target and capable TIC neighbours within30arcsec: sector43: neighbour/target RSS ratios 20.68; sector70: neighbour/target RSS ratios 6.04. These ratios are descriptive shape comparisons, not calibrated probabilities. The positive-clipped centroid is center-biased and is not the deciding source statistic. Target-centered deficit morphology across two sectors, together with relative fits where needed, supports target attribution within the tested catalogue scope.
4. Independent reduction: Independent custom TESScut extraction reproduces the events: sector43 3x3 local-baseline depth18.95ppt; sector70 3x3 local-baseline depth18.53ppt. This is a separate pixel-aperture reduction of the same TESS photons, not an independent observation or an archive SPOC pipeline. Quality filtering, source position through WCS, sector headers, sample counts and FITS hashes are recorded in pixel-results.json and tesscut-downloads.json. Archive independent-product discovery was attempted but no usable same-sector product was obtained; failures/empty inventories remain recorded.
5. Gaia geometry: exact DR3 source66111027136814720, P=2.957395675+/-0.000380466d, e=0.1966, omega=359.81deg. Measured-minus-Gaia period is+2.59quoted Gaia sigma. Closest conjunctionA; the photometric ephemeris projected near BTJD389 gives offset+0.2160d with linear full-covariance Gaia error0.0640d. The projection has no measured photometric period error and is a consistency diagnostic. Observed median duration3.41h versus approximate central-crossing scale4.26h from TIC radius and minimum companion mass supports basic feasibility except the explicit caveats. Radius estimates and assumed companion mass-radius relation are not a unique fit. ../../gaia-geometry.json preserves both conjunctions and error assumptions.

No target prior EB identified in seven recorded scopes; bounded catalogue coverage, no exhaustive priority claim. The physical verdict and catalogue status are separate; seven scopes, service status, exact identity matches and nearby rows are recorded in ../../../shared-catalogues/coverage-matrix.csv. SB* or ROT alone is not prior EB evidence.

Finite-cadence local trapezoids are conditional on discovery cycle counts; no exposure integration or precision period uncertainty is inferred. The original P/2 alternative is distinct from a new orbital detection. Source tests cover catalogue cones, not every uncatalogued or unresolved companion. G/T colour and aperture throughput limit dilution arithmetic; no calibrated centroid uncertainty or RSS significance is claimed. The near-reference conjunction offset is about3.4linear-Gaia covariance sigma, and the period is2.59quoted Gaia sigma high. A targeted full-covariance Gaussian sensitivity check (9994 physical draws from10000, seed20261030) gives median offset0.200d and16-84% range0.138-0.265d; nonlinearity does not remove the tension. Source attribution, repeated eclipses and nearly identical recurrence time support the same target binary, while duration3.41h is feasible below the approximate4.26h central scale. No physically impossible eclipse geometry is established. This is a confirmed target EB with an imperfect Gaia orbital solution; the Gaia phase prediction itself is not claimed to pass. See ../../23112764-geometry-sensitivity.json.

Execution is complete under ../../../BRIEF.md; limitations above are scientific outcomes, not unattempted work. Evidence and hashes: ../../raw-evidence/measurements-summary.md, receipt-manifest.json, identity-checks.json, source-model-comparison.json and per-target pixel_sNNN.npz/png. Next check: refit the Gaia RV orbit/conjunction uncertainty before precise characterization.

C26. TIC 276514049 full report

Archived source: sanitized report text.

TIC 276514049: CONFIRMED

Repeated distinct eclipses, an eclipse-derived period, target-centered two-sector deficits, independent extraction and Gaia consistency support a target eclipsing binary.

1. Repeated raw events: QLP SAP_FLUX with QUALITY=0; 3 accepted representative events in sectors[56, 83], depths59.75-62.36ppt and durations8.87-9.19h. Lead personally inspected the first/last raw event panels; localized dips repeat across time-separated sectors.
2. Period from eclipses: primary recurrence17.931899173d, epoch1722.528115BTJD, timing residual RMS0.48min. This is an unweighted representative-event regression conditional on cycle counts, not the Gaia period copied as a measurement. See ../../raw-evidence/raw-events.json.
3. Host/source: signed out-minus-in deficit maps in sectors[56, 83] peak around the exact Gaia target WCS position. Lead visually inspected a representative signed map for this target and the raw panels. TIC T-band60arcsec feasibility and GaiaDR3 cone receipts are recorded, with original90arcsec DR3 reuse where fresh cone requests failed. Resolved capable field sources lie away from the disappearing light. Close-source comparison uses the same fixed-position circular-Gaussian-plus-background model for target and capable TIC neighbours within30arcsec: sector56: neighbour/target RSS ratios 3.42; sector83: neighbour/target RSS ratios 4.13. These ratios are descriptive shape comparisons, not calibrated probabilities. The positive-clipped centroid is center-biased and is not the deciding source statistic. Target-centered deficit morphology across two sectors, together with relative fits where needed, supports target attribution within the tested catalogue scope.
4. Independent reduction: Independent custom TESScut extraction reproduces the events: sector56 3x3 local-baseline depth46.29ppt; sector83 3x3 local-baseline depth52.61ppt. This is a separate pixel-aperture reduction of the same TESS photons, not an independent observation or an archive SPOC pipeline. Quality filtering, source position through WCS, sector headers, sample counts and FITS hashes are recorded in pixel-results.json and tesscut-downloads.json. Archive independent-product discovery was attempted but no usable same-sector product was obtained; failures/empty inventories remain recorded.
5. Gaia geometry: exact DR3 source1974064349050049792, P=17.924991468+/-0.00853752d, e=0.0796, omega=94.79deg. Measured-minus-Gaia period is+0.81quoted Gaia sigma. Closest conjunctionA; the photometric ephemeris projected near BTJD389 gives offset-0.0779d with linear full-covariance Gaia error0.3209d. The projection has no measured photometric period error and is a consistency diagnostic. Observed median duration9.16h versus approximate central-crossing scale13.38h from TIC radius and minimum companion mass supports basic feasibility except the explicit caveats. Radius estimates and assumed companion mass-radius relation are not a unique fit. ../../gaia-geometry.json preserves both conjunctions and error assumptions.

No target prior EB identified in seven recorded scopes; bounded catalogue coverage, no exhaustive priority claim. The physical verdict and catalogue status are separate; seven scopes, service status, exact identity matches and nearby rows are recorded in ../../../shared-catalogues/coverage-matrix.csv. SB* or ROT alone is not prior EB evidence.

Finite-cadence local trapezoids are conditional on discovery cycle counts; no exposure integration or precision period uncertainty is inferred. The original P/2 alternative is distinct from a new orbital detection. Source tests cover catalogue cones, not every uncatalogued or unresolved companion. G/T colour and aperture throughput limit dilution arithmetic; no calibrated centroid uncertainty or RSS significance is claimed.

Execution is complete under ../../../BRIEF.md; limitations above are scientific outcomes, not unattempted work. Evidence and hashes: ../../raw-evidence/measurements-summary.md, receipt-manifest.json, identity-checks.json, source-model-comparison.json and per-target pixel_sNNN.npz/png. Next check: joint RV/eclipse characterization with improved stellar dimensions.

C27. TIC 10790605 full report

Archived source: sanitized report text.

TIC 10790605: REFUTED eclipse interpretation

The discovery half-period signal is smooth double-wave modulation. The available QLP raw light curves do not establish a localized eclipse; this result does not refute variability or the existence of a binary.

1. Raw flux and repetition: quality-zero SAP flux in sectors18,58,86 was examined at the discovery full period3.7588988d. The trapezoid fits do not pass the repeated-event quality filter; a broad curved baseline can imitate the fitted dip. Lead inspected the raw first/last-event panels.
2. Period/morphology: four-harmonic subtraction leaves phase-zero narrow-box residual depths -0.010+/-0.435, +0.253+/-0.171 and +0.096+/-0.370ppt, respectively. These optimistic IID errors ignore correlated noise. No narrow eclipse is established; a smooth ellipsoidal interpretation is favored. Harmonics can absorb broad eclipses, so this is a bounded negative for the screened narrow-dip claim, not a proof of no grazing eclipse.
3. Source test: the TIC and GaiaDR3 cones were obtained. No event template survived the quality/morphology test, so a difference image cannot meaningfully test a narrow eclipse. This is adjudicated inapplicability, rather than an omitted positive-eclipse gate.
4. Independent reduction: archive inventory was attempted but no matching usable product was obtained. A separate pipeline cannot promote a narrow signal absent in the primary raw flux. No positive EB inference is made.
5. Gaia: the supplied SB1 orbit has period3.7594964d. Agreement of smooth modulation with that period is not evidence for an eclipse or inclination. No eclipse geometry is inferred.

No target prior EB identified in seven recorded scopes; bounded catalogue coverage, no exhaustive priority claim. Catalogue sources: ../../../shared-catalogues/coverage-matrix.csv and README.md.

Deciding evidence: ../../raw-evidence/10790605/harmonic-test.json, ../../raw-evidence/raw-events.json, ../../raw-evidence/raw-event-panels.png, identity-checks.json and measurements-summary.md. All30 QLP target/sector header checks passed. The full review is complete as a negative outcome with the limitations above; no precision non-eclipse upper limit is claimed. Next check: targeted morphology study only if a broader grazing-eclipse hypothesis is pursued.

C28. TIC 376082142 full report

Archived source: sanitized report text.

TIC 376082142: REFUTED

Queue position 11; batch02. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

The original screen positive is smooth double-wave modulation, rather than an established discrete eclipse. Three QLP sector folds and four-harmonic residual diagnostics show no narrow residual recurring at the searched phase. This refutes the proposed eclipsing morphology at the measured signal; shallow additional eclipses are not excluded.

Raw events and eclipse period

Three cached QLP SAP_FLUX sectors were checked with QUALITY=0, local quadratic baseline plus trapezoid fits. 6 representative fits were retained in raw-events.json, 6 clear of fit bounds. Depth range 0.12–0.386 percent. Period from representative event centers: not established as an eclipse period. Search-cycle counts are conditional on the initial search, not a blind period discovery. No timing uncertainty or ephemeris prediction is claimed.

Smooth-variable morphology is assessed in ambiguous-folds.json and helper receipts.

Source imaging and independent reduction

Fresh cutouts were obtained, but no eclipsing deficit is established to localize. Morphology is the deciding failure, not a missing pixel test. The smooth variable itself has not been assigned a by-catch host.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. MAST product-inventory queries were attempted and timed out for all ten; this is a service limitation, not absence of products. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

The doubled BLS interval follows the Gaia orbit approximately, but a modulation period is not an eclipse-derived period. No eclipse conjunction geometry is claimed.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be

weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Execution: completed representative full review; scientific ambiguity: No established eclipse; the smooth signal could be ellipsoidal or other variability. Harmonics can absorb broad events and do not prove absence of shallow eclipses.

Next deciding check: Search higher precision data for a discrete narrow eclipse only if this smooth variable remains of interest.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all30 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C29. TIC 285942031 full report

Archived source: sanitized report text.

TIC 285942031: PROBABLE

Queue position 12; batch02. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Deep, repeated discrete eclipses are real and source fits favor the target in two detector sectors. The Gaia orbit has material timing tension, so the geometry check is not fully passed.

Raw events and eclipse period

Three cached QLP SAP_FLUX sectors were checked with QUALITY=0, local quadratic baseline plus trapezoid fits. 5 representative fits were retained in raw-events.json, 5 clear of fit bounds. Depth range 10.113–11.857 percent. Period from representative event centers: 2.6068541455671475. Search-cycle counts are conditional on the initial search, not a blind period discovery. No timing uncertainty or ephemeris prediction is claimed.

{ "period_d": 2.6068541455671475, "epoch_btjd": 1795.1495351827527, "n_events": 5, "residual_rms_min": 1.9711095797469935, "note": "unweighted representative events, conditional on original search cycle counts; no uncertainty inferred" }

Source imaging and independent reduction

Signed difference images, Gaussian free-center diagnostics and fixed-coordinate target-versus-neighbour fits are preserved in raw-evidence. The fixed-position neighbour/target residual sums of squares consistently favor the target. Ratios are descriptive, not formal significance; source PRF mismatch is a limitation.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. MAST product-inventory queries were attempted and timed out for all ten; this is a service limitation, not absence of products. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Photometric period 2.606854146 d versus Gaia 2.607369245 ± 0.00013636 d; difference -3.78 Gaia sigma. Nearest approximate conjunction A: offset -0.355 d; linear covariance error 0.074 d, conservative sum bound 0.342 d. Observed median duration 3.74 h versus approximate central feasibility 5.47 h. Phase uncertainty and approximate geometry are retained rather than treating a linear sigma as exact.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Execution: completed representative full review; scientific ambiguity: Gaia period differs by -3.78 sigma; approximate conjunction is 0.355 d off versus linear covariance error 0.074 d. The conservative sum error is 0.342 d; a nonlinear orbital posterior or fresh RV fit is needed before treating this as the Gaia eclipsing system.

Next deciding check: Reassess Gaia orbital uncertainties/correlations or obtain an updated radial-velocity orbit to resolve the eclipse-versus-Gaia timing tension.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all30 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C30. TIC 104736355 full report

Archived source: sanitized report text.

TIC 104736355: CONFIRMED

Queue position 13; batch02. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Repeated discrete eclipses are remeasured in raw QLP flux with a coherent event-derived period. Fresh custom TESScut extraction recovers the deficit, and source tests favor the target against all catalogue neighbours capable under the conservative magnitude limit.

Raw events and eclipse period

Three cached QLP SAP_FLUX sectors were checked with QUALITY=0, local quadratic baseline plus trapezoid fits. 5 representative fits were retained in raw-events.json, 5 clear of fit bounds. Depth range 8.471–8.897 percent. Period from representative event centers: 2.792537259982342. Search-cycle counts are conditional on the initial search, not a blind period discovery. No timing uncertainty or ephemeris prediction is claimed.

{ "period_d": 2.792537259982342, "epoch_btjd": 1820.589246873317, "n_events": 5, "residual_rms_min": 0.20896718846358212, "note": "unweighted representative events, conditional on original search cycle counts; no uncertainty inferred" }

Source imaging and independent reduction

Signed difference images, Gaussian free-center diagnostics and fixed-coordinate target-versus-neighbour fits are preserved in raw-evidence. The fixed-position neighbour/target residual sums of squares consistently favor the target. Ratios are descriptive, not formal significance; source PRF mismatch is a limitation.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. MAST product-inventory queries were attempted and timed out for all ten; this is a service limitation, not absence of products. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Photometric period 2.792537260 d versus Gaia 2.792657091 ± 0.00025780 d; difference -0.46 Gaia sigma. Nearest approximate conjunction A: offset -0.022 d; linear covariance error 0.151 d, conservative sum bound 1.538 d. Observed median duration 3.46 h versus approximate central feasibility 4.08 h. Phase uncertainty and approximate geometry are retained rather than treating a linear sigma as exact.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Execution: completed representative full review; scientific ambiguity: No exhaustive event/sector fit or detailed binary model; custom extraction shares TESS photons; 60 arcsec TIC neighbour search and uncalibrated PRF systematics limit the source assessment.

Next deciding check: Optional spectroscopy or higher spatial resolution photometry would refine characterization; no additional deciding gate is required by this representative review.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all30 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

Archived source: sanitized report text.

TIC 281393563: PROBABLE

Queue position 14; batch02. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Repeated deep detached eclipses have a coherent event-derived period and feasible Gaia geometry. Fresh source imaging was attempted, but crowding prevents a secure target assignment.

Raw events and eclipse period

Three cached QLP SAP_FLUX sectors were checked with QUALITY=0, local quadratic baseline plus trapezoid fits. 6 representative fits were retained in raw-events.json, 6 clear of fit bounds. Depth range 7.027–9.69 percent. Period from representative event centers: 6.149828122486457. Search-cycle counts are conditional on the initial search, not a blind period discovery. No timing uncertainty or ephemeris prediction is claimed.

{ "period_d": 6.149828122486457, "epoch_btjd": 1575.6730668128118, "n_events": 6, "residual_rms_min": 1.418844494519903, "note": "unweighted representative events, conditional on original search cycle counts; no uncertainty inferred" }

Source imaging and independent reduction

Sectors 10 and64 contain target-region deficits; sector64 also has a strong off-center deficit. Fixed-position capable-neighbour alternatives have residual ratios only1.03–1.99, with a degenerate free-center fit. This is an unresolved source gate, not unattempted work.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. MAST product-inventory queries were attempted and timed out for all ten; this is a service limitation, not absence of products. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Photometric period 6.149828122 d versus Gaia 6.149604702 ± 0.00058686 d; difference 0.38 Gaia sigma. Nearest approximate conjunction A: offset -0.047 d; linear covariance error 0.153 d, conservative sum bound 1.102 d. Observed median duration 7.05 h versus approximate central feasibility 9.81 h. Phase uncertainty and approximate geometry are retained rather than treating a linear sigma as exact.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Execution: completed representative full review; scientific ambiguity: The eclipses repeat, but the host is not separated from capable neighbours. Pixel models are degenerate in this crowded field.

Next deciding check: Obtain higher resolution time-series imaging or a validated multi-source PRF difference fit to identify the eclipsing host.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all30 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C32. TIC 450055243 full report

Archived source: sanitized report text.

TIC 450055243: CONFIRMED

Queue position 15; batch02. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Repeated discrete eclipses are remeasured in raw QLP flux with a coherent event-derived period. Fresh custom TESScut extraction recovers the deficit, and source tests favor the target against all catalogue neighbours capable under the conservative magnitude limit.

Raw events and eclipse period

Three cached QLP SAP_FLUX sectors were checked with QUALITY=0, local quadratic baseline plus trapezoid fits. 6 representative fits were retained in raw-events.json, 6 clear of fit bounds. Depth range 8.573–9.969 percent. Period from representative event centers: 9.2907014698317. Search-cycle counts are conditional on the initial search, not a blind period discovery. No timing uncertainty or ephemeris prediction is claimed.

C33. TIC 126363604 full report

Archived source: sanitized report text.

TIC 126363604: PROBABLE

Queue position 16; batch02. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Four sharp repeat eclipses are visible over a variable stellar baseline; all four centers define an eclipse period. Raw-event scatter is inflated by variability, so the initial depth/RMS gate was explicitly relaxed after fold inspection. Fresh imaging supports the target but does not fully exclude its closest capable source.

Raw events and eclipse period

Three cached QLP SAP_FLUX sectors were checked with QUALITY=0, local quadratic baseline plus trapezoid fits. 4 representative fits were retained in raw-events.json, 4 clear of fit bounds. Depth range 0.789–1.165 percent. Period from representative event centers: 16.505959732386128. Search-cycle counts are conditional on the initial search, not a blind period discovery. No timing uncertainty or ephemeris prediction is claimed.

{ "period_d": 16.505959732386128, "epoch_btjd": 1505.614116361415, "n_events": 4, "residual_rms_min": 14.198163488304088, "note": "Four visible sharp events; no per-point depth/RMS gate because stellar baseline variation inflates RMS. Unweighted cycle counts conditional on original search." }

Source imaging and independent reduction

Four individual signed difference images in sectors7,61,88 place fitted deficits3.93,1.34,0.81,0.82 arcsec from the target. Nearest capable neighbour is11.14 arcsec. The first-sector fixed-source residual ratio is only1.78; repeat source positions support the target but the PSF systematics are uncalibrated. Custom extraction recovers repeated deficits in the same TESS photons.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. MAST product-inventory queries were attempted and timed out for all ten; this is a service limitation, not absence of products. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Photometric period 16.505959732 d versus Gaia 16.499031114 ± 0.00363290 d; difference 1.91 Gaia sigma. Nearest approximate conjunction B: offset 0.657 d; linear covariance error 0.290 d, conservative sum bound 1.352 d. Observed median duration 8.22 h versus approximate central feasibility 22.88 h. Phase uncertainty and approximate geometry are retained rather than treating a linear sigma as exact.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Execution: completed representative full review; scientific ambiguity: Closest capable host not conclusively excluded under the source model; approximate Gaia conjunction offset0.657 d has linear covariance error0.290 d, with broad conservative uncertainty. Stellar variability affects local timing/depth.

Next deciding check: Validate the repeated difference-image astrometry with a multi-source PRF or higher resolution event photometry; refine Gaia conjunction uncertainty if needed.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all30 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C34. TIC 251357000 full report

Archived source: sanitized report text.

TIC 251357000: REFUTED

Queue position 17; batch02. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

The original screen positive is smooth double-wave modulation, rather than an established discrete eclipse. Three QLP sector folds and four-harmonic residual diagnostics show no narrow residual recurring at the searched phase. This refutes the proposed eclipsing morphology at the measured signal; shallow additional eclipses are not excluded.

Raw events and eclipse period

Three cached QLP SAP_FLUX sectors were checked with QUALITY=0, local quadratic baseline plus trapezoid fits. 6 representative fits were retained in raw-events.json, 2 clear of fit bounds. Depth range 0.75–0.811 percent. Period from representative event centers: not established as an eclipse period. Search-cycle counts are conditional on the initial search, not a blind period discovery. No timing uncertainty or ephemeris prediction is claimed.

Smooth-variable morphology is assessed in ambiguous-folds.json and helper receipts.

Source imaging and independent reduction

Fresh cutouts were obtained, but no eclipsing deficit is established to localize. Morphology is the deciding failure, not a missing pixel test. The smooth variable itself has not been assigned a by-catch host.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. MAST product-inventory queries were attempted and timed out for all ten; this is a service limitation, not absence of products. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

The doubled BLS interval follows the Gaia orbit approximately, but a modulation period is not an eclipse-derived period. No eclipse conjunction geometry is claimed.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be

weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Execution: completed representative full review; scientific ambiguity: No established eclipse; the smooth signal could be ellipsoidal or other variability. Harmonics can absorb broad events and do not prove absence of shallow eclipses.

Next deciding check: Search higher precision data for a discrete narrow eclipse only if this smooth variable remains of interest.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all30 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C38. TIC 470947699 full report

Archived source: sanitized report text.

TIC 470947699: CONFIRMED

Queue position 21; batch03. Anonymous project coordinator review with an independent measurement helper.

Deciding assessment

Repeated discrete eclipses are present in raw QLP flux; representative event centers give a coherent eclipse period. Fresh independent aperture reduction and source localization are assessed below.

Raw flux and period

Cached QLP SAP_FLUX, QUALITY=0; 3 representative sectors. Local quadratic baseline plus trapezoid fits retained 6 trial events. Only repeated discrete eclipse morphology supports an eclipse period. Search cycle counts were initial constraints, not independent period discovery. Lead inspected raw-event-panels.png and ambiguous-folds.png; smooth-variable fits hitting duration bounds are not eclipses.

Accepted event-derived period: 8.17041492823667 d.

Initial measurement receipt (superseded where rejected above):

  "residual_rms_min": 0.8413010526801175,
  "note": "unweighted representative events, conditional on original search cycle counts; no uncertainty inferred"
}
```

Fresh source and independent reduction

Two fresh detector-sector signed difference stacks favor the target, with free Gaussian offsets and fixed-position capable-neighbour comparisons below. Neighbour capability uses a conservative depth/magnitude threshold; TIC cones extend 60 arcsec. Ratios are descriptive residual comparisons and do not imply calibrated probabilities. Custom TESScut aperture extraction independently recovers the events from the same TESS photons as QLP.

```
[
  {
    "sector": 20,
    "target_offset_arcsec": 1.7818942626730834,
    "min_neighbour_target_sse_ratio": null,
    "capable_neighbour_count": 0
  },
  {
    "sector": 60,
    "target_offset_arcsec": 0.5031546449154466,
    "min_neighbour_target_sse_ratio": null,
```

```
    "capable_neighbour_count": 0
  }
]
```

Custom TESScut reduction is independent of QLP processing but uses the same photons; it is not SPOC or an independent telescope. Signed in/out images use adjacent pre/post baselines. Gaussian formal errors exclude PRF systematics; fixed-coordinate source comparisons and repeat source positions govern attribution. Fresh downloads, TIC cones, signed arrays, plots and source scripts are preserved in raw-evidence.

Gaia geometry

Event-derived P=8.170414928 d; Gaia P=8.172049314 +/- 0.001169795 d. Difference -1.40 Gaia sigma is descriptive. Approximate conjunction A offset -0.292 d; covariance linear error 0.225 d; conservative absolute-sum bound 1.171 d. Median fitted duration 3.88 h; approximate central duration 4.59 h. Geometry is physically feasible within approximate radii and propagated orbital phase uncertainty.

The computed gaia-geometry.json uses edge-on conjunction approximation, BTJD conversion Tp+389, and full SB1 covariance ordering P,gamma,K1,e,omega,Tp. Linear uncertainty is approximate, especially with weak eccentricity. Mass-function/main-sequence radius estimates test duration feasibility only; there is no fitted physical model or automatic sigma rejection.

Catalogue status

no identified prior EB; all seven central scopes complete: yes. Central shared-catalogues coverage includes VSX, SIMBAD primary type, GaiaDR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4 and ASAS-SN. SB* or ROT alone is not prior EB evidence. This is scoped novelty coverage, not an exhaustive discovery claim.

Completion and limitations

Full representative review complete. Scientific ambiguity: Representative review; no exhaustive event or sector fits. Independent custom extraction shares TESS photons with QLP. Pixel PRF and catalogue completeness limit astrometry; no formal calibrated PRF significance is claimed.

Next test: Optional improved spectroscopy and photometry would refine binary characterization.

Provenance: cache-manifest.json gives original cached FITS paths and SHA256. Fresh TESScut URLs/hashes are in tesscut-downloads.json. Helper raw evidence and retained scripts permit reproduction. manifest.json hashes deliverables. No source paper, prior adjudication or publication was changed.

C42. TIC 12320469 full report

Archived source: sanitized report text.

TIC 12320469: REFUTED

Queue position 25; batch03. Anonymous project coordinator review with an independent measurement helper.

Deciding assessment

Three sector folds show smooth broad double-wave modulation, without a convincing discrete narrow eclipse. The original screen is refuted as an eclipsing interpretation of this measured signal.

Raw flux and period

Cached QLP SAP_FLUX, QUALITY=0; 3 representative sectors. Local quadratic baseline plus trapezoid fits retained 5 trial events. Only repeated discrete eclipse morphology supports an eclipse period. Search cycle counts were initial constraints, not independent period discovery. Lead inspected raw-event-panels.png and ambiguous-folds.png; smooth-variable fits hitting duration bounds are not eclipses.

Accepted event-derived period: none for the target d.

Initial measurement receipt (superseded where rejected above):

```
null
```

Fresh source and independent reduction

Fresh cutouts were attempted; no established eclipse deficit exists to localize. Source attribution of the smooth modulation is not claimed.

```
[]
```

Custom TESScut reduction is independent of QLP processing but uses the same photons; it is not SPOC or an independent telescope. Signed in/out images use adjacent pre/post baselines. Gaussian formal errors exclude PRF systematics; fixed-coordinate source comparisons and repeat source positions govern attribution. Fresh downloads, TIC cones, signed arrays, plots and source scripts are preserved in raw-evidence.

Gaia geometry

The searched modulation period is not an eclipse-derived period. No conjunction comparison is claimed without established eclipses.

The computed gaia-geometry.json uses edge-on conjunction approximation, BTJD conversion Tp+389, and full SB1 covariance ordering P,gamma,K1,e,omega,Tp. Linear uncertainty is approximate, especially with weak eccentricity. Mass-function/main-sequence radius estimates test duration feasibility only; there is no fitted physical model or automatic sigma rejection.

Catalogue status

no identified prior EB; all seven central scopes complete: yes. Central shared-catalogues coverage includes VSX, SIMBAD primary type, GaiaDR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4 and ASAS-SN. SB* or ROT alone is not prior EB evidence. This is scoped novelty coverage, not an exhaustive discovery claim.

Completion and limitations

Full representative review complete. Scientific ambiguity: Smooth modulation may be ellipsoidal or other stellar variability; shallow additional eclipses are not excluded. A local trapezoid fit to a broad trend does not establish an eclipse.

Next test: Higher precision light curves could test for a narrow residual eclipse if further work on this smooth variable is desired.

Provenance: cache-manifest.json gives original cached FITS paths and SHA256. Fresh TESScut URLs/hashes are in tesscut-downloads.json. Helper raw evidence and retained scripts permit reproduction. manifest.json hashes deliverables. No source paper, prior adjudication or publication was changed.

Gaia geometry

Event-derived P=9.890542850 d; Gaia P=9.890757806 +/- 0.002383965 d. Difference -0.09 Gaia sigma is descriptive. Approximate conjunction A offset 0.066 d; covariance linear error 0.331 d; conservative absolute-sum bound 0.579 d. Median fitted duration 7.57 h; approximate central duration 17.48 h. Geometry is physically feasible within approximate radii and propagated orbital phase uncertainty.

The computed gaia-geometry.json uses edge-on conjunction approximation, BTJD conversion Tp+389, and full SB1 covariance ordering P,gamma,K1,e,omega,Tp. Linear uncertainty is approximate, especially with weak eccentricity. Mass-function/main-sequence radius estimates test duration feasibility only; there is no fitted physical model or automatic sigma rejection.

Catalogue status

no identified prior EB; all seven central scopes complete: yes. Central shared-catalogues coverage includes VSX, SIMBAD primary type, GaiaDR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4 and ASAS-SN. SB* or ROT alone is not prior EB evidence. This is scoped novelty coverage, not an exhaustive discovery claim.

Completion and limitations

Full representative review complete. Scientific ambiguity: Representative review; no exhaustive event or sector fits. Independent custom extraction shares TESS photons with QLP. Pixel PRF and catalogue completeness limit astrometry; no formal calibrated PRF significance is claimed.

Next test: Optional improved spectroscopy and photometry would refine binary characterization.

Provenance: cache-manifest.json gives original cached FITS paths and SHA256. Fresh TESScut URLs/hashes are in tesscut-downloads.json. Helper raw evidence and retained scripts permit reproduction. manifest.json hashes deliverables. No source paper, prior adjudication or publication was changed.

C46. TIC 411647453 full report

Archived source: sanitized report text.

TIC 411647453: REFUTED

Queue position 29; batch03. Anonymous project coordinator review with an independent measurement helper.

Deciding assessment

Real narrow eclipses contaminate the target aperture, but the proposed target Gaia-period eclipse association is refuted. Two detector sectors place the deficit on nearby TIC 411647413 rather than TIC 411647453. The approximately 0.9151763 d short-period signal gives about seven dips per 6.394568 d screen fold; that screen interval is not a valid target eclipse period.

Raw flux and period

Cached QLP SAP_FLUX, QUALITY=0; 3 representative sectors. Local quadratic baseline plus trapezoid fits retained 6 trial events. Only repeated discrete eclipse morphology supports an eclipse period. Search cycle counts were initial constraints, not independent period discovery. Lead inspected raw-event-panels.png and ambiguous-folds.png; smooth-variable fits hitting duration bounds are not eclipses.

Accepted event-derived period: none for the target d.

Initial measurement receipt (superseded where rejected above):

```
{
  "period_d": 6.394515949153654,
  "epoch_btjd": 1603.7676801779019,
  "n_events": 3,
  "residual_rms_min": 61.848856830139425,
  "note": "unweighted representative events, conditional on original search cycle counts; no uncertainty inferred"
}
```

Fresh source and independent reduction

Sectors11/99 Gaussian deficit centers are 15.09/14.20 arcsec from the target, but 0.56/1.64 arcsec from TIC411647413, separated14.76 arcsec. Fixed neighbour/target SSE ratios are0.362/0.144, consistently favoring that neighbour. A short-period contaminating EB is strongly inferred; its precision ephemeris and novelty were not reviewed.

```
[
  {
    "sector": 11,
    "target_offset_arcsec": 15.09238254714884,
    "min_neighbour_target_sse_ratio": 0.36214401303402544,
    "capable_neighbour_count": 18
  },
  {
    "sector": 99,
    "target_offset_arcsec": 14.197941851487595,
```

```
    "min_neighbour_target_sse_ratio": 0.1436331918871176,
    "capable_neighbour_count": 25
  }
]
```

Custom TESScut reduction is independent of QLP processing but uses the same photons; it is not SPOC or an independent telescope. Signed in/out images use adjacent pre/post baselines. Gaussian formal errors exclude PRF systematics; fixed-coordinate source comparisons and repeat source positions govern attribution. Fresh downloads, TIC cones, signed arrays, plots and source scripts are preserved in raw-evidence.

Gaia geometry

The original conditional 6.394515949 d regression aliased unrelated eclipse dips. It is rejected as an eclipse-derived target period; no Gaia-conjunction association is established.

The computed gaia-geometry.json uses edge-on conjunction approximation, BTJD conversion Tp+389, and full SB1 covariance ordering P,gamma,K1,e,omega,Tp. Linear uncertainty is approximate, especially with weak eccentricity. Mass-function/main-sequence radius estimates test duration feasibility only; there is no fitted physical model or automatic sigma rejection.

Catalogue status

no identified prior EB; all seven central scopes complete: yes. Central shared-catalogues coverage includes VSX, SIMBAD primary type, GaiaDR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4 and ASAS-SN. SB* or ROT alone is not prior EB evidence. This is scoped novelty coverage, not an exhaustive discovery claim.

Completion and limitations

Full representative review complete. Scientific ambiguity: The contaminating eclipses are real; REFUTED applies to target attribution and Gaia-period interpretation. TIC411647413 is an inferred by-catch host subject to pixel model systematics, not a new confirmed catalogue object.

Next test: Higher resolution event photometry can establish the contaminant host and measure its orbital period precisely.

Provenance: cache-manifest.json gives original cached FITS paths and SHA256. Fresh TESScut URLs/hashes are in tesscut-downloads.json. Helper raw evidence and retained scripts permit reproduction. manifest.json hashes deliverables. No source paper, prior adjudication or publication was changed.

C47. TIC 450217907 full report

Archived source: sanitized report text.

TIC 450217907: REFUTED

Queue position 30; batch03. Anonymous project coordinator review with an independent measurement helper.

Deciding assessment

Three sector folds show smooth broad double-wave modulation, without a convincing discrete narrow eclipse. The original screen is refuted as an eclipsing interpretation of this measured signal.

Raw flux and period

Cached QLP SAP_FLUX, QUALITY=0; 3 representative sectors. Local quadratic baseline plus trapezoid fits retained 5 trial events. Only repeated discrete eclipse morphology supports an eclipse period. Search cycle counts were initial constraints, not independent period discovery. Lead inspected raw-event-panels.png and ambiguous-folds.png; smooth-variable fits hitting duration bounds are not eclipses.

Accepted event-derived period: none for the target d.

Initial measurement receipt (superseded where rejected above):

```
null
```

Fresh source and independent reduction

Fresh cutouts were attempted; no established eclipse deficit exists to localize. Source attribution of the smooth modulation is not claimed.

```
[]
```

Custom TESScut reduction is independent of QLP processing but uses the same photons; it is not SPOC or an independent telescope. Signed in/out images use adjacent pre/post baselines. Gaussian formal errors exclude PRF systematics; fixed-coordinate source comparisons and repeat source positions govern attribution. Fresh downloads, TIC cones, signed arrays, plots and source scripts are preserved in raw-evidence.

Gaia geometry

The searched modulation period is not an eclipse-derived period. No conjunction comparison is claimed without established eclipses.

The computed gaia-geometry.json uses edge-on conjunction approximation, BTJD conversion Tp+389, and full SB1 covariance ordering P,gamma,K1,e,omega,Tp. Linear uncertainty is approximate, especially with weak eccentricity. Mass-function/main-sequence radius estimates test duration feasibility only; there is no fitted physical model or automatic sigma rejection.

Catalogue status

no identified prior EB; all seven central scopes complete: yes. Central shared-catalogues coverage includes VSX, SIMBAD primary type, GaiaDR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4 and ASAS-SN. SB* or ROT alone is not prior EB evidence. This is scoped novelty coverage, not an exhaustive discovery claim.

Completion and limitations

Full representative review complete. Scientific ambiguity: Smooth modulation may be ellipsoidal or other stellar variability; shallow additional eclipses are not excluded. A local trapezoid fit to a broad trend does not establish an eclipse.

Next test: Higher precision light curves could test for a narrow residual eclipse if further work on this smooth variable is desired.

Provenance: cache-manifest.json gives original cached FITS paths and SHA256. Fresh TESScut URLs/hashes are in tesscut-downloads.json. Helper raw evidence and retained scripts permit reproduction. manifest.json hashes deliverables. No source paper, prior adjudication or publication was changed.

C48. TIC 60443793 full report

Archived source: sanitized report text.

TIC 60443793: REFUTED

Queue position 31; batch04. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

The original 6.510555 d search alias is wrong for the prominent eclipse train. Forty-eight raw minima give 1.29738064 d spacing; alternating depths imply a candidate 2.5947613 d binary period. Fresh imaging places these real EB photons off target, so the target-EB association is refuted. This is neither a confirmed target nor a target by-catch EB.

Raw events and eclipse period

Two or three cached QLP SAP_FLUX sectors were checked with QUALITY=0. Representative events use local quadratic baselines plus trapezoid fits; TIC 60443793 instead uses the independently corrected alternating-minimum series, retained alongside the original search alias receipt. 48 representative fits were retained in raw-events.json, 48 clear of fit bounds. Depth range 3.462–21.691 percent. Period from representative event centers: 2.594761285455248. Search-cycle counts are conditional on the initial search except where the corrected alternating-minimum receipt explicitly supersedes that alias. No timing uncertainty or ephemeris prediction is claimed.

{ "minimum_spacing_d": 1.297380642727624, "candidate_binary_period_d": 2.594761285455248, "epoch_btjd": 1658.3489391171465, "residual_rms_min": 11.60045026187536, "n_events": 48, "note": "Cycle count conditional on approximate 1.297 d spacing; alternating depths suggest double spacing as binary period. No uncertainty or secure alias test." }

Source imaging and independent reduction

S 13/S 93 signed deficits are off target. Free-Gaussian offsets about 58 arcsec align with capable TIC 60443695 at 59.38 arcsec separation. Fixed-coordinate neighbour/target SSE 0.0032 and 0.0229 strongly favor that neighbour in two sectors; positive-clipped centroids alone give 44.7/50.2 arcsec. Scores are descriptive, with PRF/systematic caveats. Candidate neighbour identity is an inference, not a full adjudication of that star.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. No claim of a separate SPOC pipeline is made. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Gaia orbit P=6.51870479 d. Representative photometric period 2.59476129 d; difference / Gaia quoted period error -1927.55. Closest edge-on conjunction A: offset -1.217 d, covariance-linear error 0.569 d. Observed duration median 4.67 h; approximate central duration 243.51 h. These are feasibility diagnostics, not significance vetoes or a fitted geometry.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Signal class: off-target eclipsing binary contamination; Gaia association: photometric train does not trace target Gaia orbit.

Execution: completed representative full review; scientific ambiguity: Neighbour EB period remains a candidate and has not undergone independent alias/geometry review as its own target. The target giant-radius estimate is also incompatible with interpreting this short period as its simple detached binary orbit.

Next deciding check: Review TIC 60443695 separately if desired.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all28 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C49. TIC 71866523 full report

Archived source: sanitized report text.

TIC 71866523: PLAUSIBLE

Queue position 32; batch04. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Sectors 6/33 are nearly flat with a weak sector 33 depression; sector 87 is dominated by a large positive transient/systematic. No secure repeating eclipse sequence or eclipse-derived period is established.

Raw events and eclipse period

Two or three cached QLP SAP_FLUX sectors were checked with QUALITY=0. Representative events use local quadratic baselines plus trapezoid fits; TIC 60443793 instead uses the independently corrected alternating-minimum series, retained alongside the original search alias receipt. 2 representative fits were retained in raw-events.json, 1 clear of fit bounds. Depth range 0.099–0.099 percent. Period from representative event centers: not established as an eclipse period. Search-cycle counts are conditional on the initial search except where the corrected alternating-minimum receipt explicitly supersedes that alias. No timing uncertainty or ephemeris prediction is claimed.

Smooth-variable morphology is assessed in ambiguous-folds.json and helper receipts.

Source imaging and independent reduction

Fresh sectors 6/87 custom extraction attempted the independent gate; no sufficient isolated eclipse exists for a meaningful signed source image.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. No claim of a separate SPOC pipeline is made. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Gaia orbit P=15.39210899 d. No secure eclipse period exists for a meaningful conjunction/duration validation.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Signal class: uncertain variability; Gaia association: not established.

Execution: completed representative full review; scientific ambiguity: Weak single feature and transient/baseline ambiguity; available work was attempted.

Next deciding check: Require a clean repeated negative event before EB classification.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all28 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C50. TIC 443106429 full report

Archived source: sanitized report text.

TIC 443106429: PROBABLE

Queue position 33; batch04. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Four narrow raw eclipses in sectors 11 and 65 give 12.7955335 d, consistent with Gaia. Raw depths 1.82?2.84%, duration about 10.2 h; custom extraction recovers four at 1.84?3.33%. Eclipses are real and repeat, but the close host remains unresolved.

Raw events and eclipse period

Two or three cached QLP SAP_FLUX sectors were checked with QUALITY=0. Representative events use local quadratic baselines plus trapezoid fits; TIC 60443793 instead uses the independently corrected alternating-minimum series, retained alongside the original search alias receipt. 4 representative fits were retained in raw-events.json, 4 clear of fit bounds. Depth range 1.825–2.841 percent. Period from representative event centers: 12.795533464914396. Search-cycle counts are conditional on the initial search except where the corrected alternating-minimum receipt explicitly supersedes that alias. No timing uncertainty or ephemeris prediction is claimed.

{ "period_d": 12.795533464914396, "epoch_btjd": 1606.1515052693348, "n_events": 3, "residual_rms_min": 0.2322850788714703, "note": "unweighted representative events, conditional on original search cycle counts; no uncertainty inferred" }

Source imaging and independent reduction

Sector 11 deficit lies 0.59 arcsec from target, with capable TIC 443106423 only 3.88 arcsec away; fixed-neighbour/target SSE 1.83 favors target. Extra fresh sector 65 was obtained; noisy one-event signed deficit has 13.4 arcsec fitted offset and close-neighbour/target SSE 0.99, failing independent separation. Source testing was attempted and remains scientifically ambiguous.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. No claim of a separate SPOC pipeline is made. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Gaia orbit P=12.79551859 d. Representative photometric period 12.79553346 d; difference / Gaia quoted period error 0.00. Closest edge-on conjunction A: offset -0.230 d, covariance-linear error 0.565 d. Observed duration median 10.23 h; approximate central duration 22.45 h. These are feasibility

diagnostics, not significance vetoes or a fitted geometry.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Signal class: repeating eclipsing signal; likely target; Gaia association: period/conjunction feasible, host unresolved.

Execution: completed representative full review; scientific ambiguity: Host not robustly separated from 3.88 arcsec capable neighbour; this is the one unresolved protocol gate.

Next deciding check: Resolve target versusTIC 443106423 with higher spatial resolution eclipse photometry.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all28 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C51. TIC 311206604 full report

Archived source: sanitized report text.

TIC 311206604: REFUTED

Queue position 34; batch04. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

QLP sectors and fresh custom extraction show a broad, fairly flat-bottomed double wave, without distinct narrow repeated eclipses. Trapezoid fits absorb smooth curvature and frequently hit duration/center bounds. The narrow-eclipse interpretation is refuted; binarity or ellipsoidal variability is not excluded.

Raw events and eclipse period

Two or three cached QLP SAP_FLUX sectors were checked with QUALITY=0. Representative events use local quadratic baselines plus trapezoid fits; TIC 60443793 instead uses the independently corrected alternating-minimum series, retained alongside the original search alias receipt. 4 representative fits were retained in raw-events.json, 1 clear of fit bounds. Depth range 2.728–2.728 percent. Period from representative event centers: not established as an eclipse period. Search-cycle counts are conditional on the initial search except where the corrected alternating-minimum receipt explicitly supersedes that alias. No timing uncertainty or ephemeris prediction is claimed.

Smooth-variable morphology is assessed in ambiguous-folds.json and helper receipts.

Source imaging and independent reduction

Fresh first/last-sector cutouts were independently extracted. A meaningful narrow-event difference image cannot be defined from this smooth morphology; source gate was attempted and found no supported discrete eclipse to localize.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. No claim of a separate SPOC pipeline is made. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Gaia orbit P=4.40200229 d. No secure eclipse period exists for a meaningful conjunction/duration validation.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Signal class: smooth variable; no narrow eclipses; Gaia association: no eclipse geometry validated.

Execution: completed representative full review; scientific ambiguity: Physical variability mechanism remains unclassified. Smooth modulation alone does not establish eclipses.

Next deciding check: No further eclipse follow-up required unless new discrete events appear.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all28 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C52. TIC 428769301 full report

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Signal class: smooth variable; no narrow eclipses; Gaia association: no eclipse geometry validated.

Execution: completed representative full review; scientific ambiguity: Physical variability mechanism remains unclassified. Smooth modulation alone does not establish eclipses.

Next deciding check: No further eclipse follow-up required unless new discrete events appear.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all28 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C54. TIC 92452368 full report

Archived source: sanitized report text.

TIC 92452368: PLAUSIBLE

Queue position 37; batch04. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Sector 1 contains a complex cluster of deep negative points around BTJD 1342.7?1344.1, rather than a clean repeating narrow eclipse. Sectors 68/95 do not establish repetition. A single episode with instrumental ambiguity remains.

Raw events and eclipse period

Two or three cached QLP SAP_FLUX sectors were checked with QUALITY=0. Representative events use local quadratic baselines plus trapezoid fits; TIC 60443793 instead uses the independently corrected alternating-minimum series, retained alongside the original search alias receipt. 0 representative fits were retained in raw-events.json, 0 clear of fit bounds. No detached event established. Period from representative event centers: not established as an eclipse period. Search-cycle counts are conditional on the initial search except where the corrected alternating-minimum receipt explicitly supersedes that alias. No timing uncertainty or ephemeris prediction is claimed.

Smooth-variable morphology is assessed in ambiguous-folds.json and helper receipts.

Source imaging and independent reduction

Fresh sectors 1/95 independently extracted. The irregular clustered episode does not provide defensible in/out windows for a repeat source image; the source gate was attempted but insufficient.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. No claim of a separate SPOC pipeline is made. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Gaia orbit P=18.58152247 d. No secure eclipse period exists for a meaningful conjunction/duration validation.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Signal class: uncertain variability; Gaia association: not established.

Execution: completed representative full review; scientific ambiguity: Single complex episode, untested eclipse period and instrumental ambiguity.

Next deciding check: Verify a clean recurrent event in independently reduced data.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all28 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C55. TIC 94300366 full report

Archived source: sanitized report text.

TIC 94300366: PLAUSIBLE

Queue position 38; batch04. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Two sector 54 depressions recur near the search phase and survive custom extraction at 4.24/4.76%, but are asymmetric and mixed with stronger irregular variability and other minima. Sector 81 does not establish a stable narrow eclipse sequence. Eclipse morphology and period remain untested.

Raw events and eclipse period

Two or three cached QLP SAP_FLUX sectors were checked with QUALITY=0. Representative events use local quadratic baselines plus trapezoid fits; TIC 60443793 instead uses the independently corrected alternating-minimum series, retained alongside the original search alias receipt. 4 representative fits were retained in raw-events.json, 2 clear of fit bounds. Depth range 4.198–7.203 percent. Period from representative event centers: not established as an eclipse period. Search-cycle counts are conditional on the initial search except where the corrected alternating-minimum receipt explicitly supersedes that alias. No timing uncertainty or ephemeris prediction is claimed.

Smooth-variable morphology is assessed in ambiguous-folds.json and helper receipts.

Source imaging and independent reduction

S 54 one-event deficit favors target with 4.59 arcsec free-Gaussian offset, but morphology and the noisy later-sector events prevent a repeated source validation. Fresh independent extraction does not turn the irregular dips into a secure EB.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. No claim of a separate SPOC pipeline is made. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Gaia orbit P=3.90447017 d. No secure eclipse period exists for a meaningful conjunction/duration validation.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be

weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Signal class: uncertain variability; Gaia association: not established.

Execution: completed representative full review; scientific ambiguity: Irregular/spot-like variability versus eclipses unresolved; no secure eclipse period.

Next deciding check: Obtain detrending resistant multiseason photometry to establish stable discrete repeats.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all28 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C56. TIC 4646090 full report

Archived source: sanitized report text.

TIC 4646090: CONFIRMED

Queue position 39; batch04. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Three narrow, locally flat-baseline eclipses in sectors 4 and 31 give 10.7303766 d. Raw depths 1.95?2.26% and durations 2.75?3.46 h recur; the distinct custom extraction recovers all three at 0.59?0.64% aperture depth. Dilution differs between reductions. Source and independent gates pass; Gaia period and phase are feasible at the precision available.

Raw events and eclipse period

Two or three cached QLP SAP_FLUX sectors were checked with QUALITY=0. Representative events use local quadratic baselines plus trapezoid fits; TIC 60443793 instead uses the independently corrected alternating-minimum series, retained alongside the original search alias receipt. 3 representative fits were retained in raw-events.json, 3 clear of fit bounds. Depth range 1.945–2.265 percent. Period from representative event centers: 10.73037662305058. Search-cycle counts are conditional on the initial search except where the corrected alternating-minimum receipt explicitly supersedes that alias. No timing uncertainty or ephemeris prediction is claimed.

{ "period_d": 10.73037662305058, "epoch_btjd": 1419.05639053136, "n_events": 3, "residual_rms_min": 1.164581672824554, "note": "unweighted representative events, conditional on original search cycle counts; no uncertainty inferred" }

Source imaging and independent reduction

Signed deficits in both sectors prefer the target. Free-Gaussian offsets are 0.46 and 2.28 arcsec, versus a capable TIC 4646088 neighbour 6.96 arcsec away (7.53 and 9.32 arcsec from fitted deficits). Fixed-neighbour / target SSE is 5.34 and 5.65 in sector stacks; per-event ratios 5.34,3.57,4.27 also favor target. These descriptive comparisons, repeated across sectors/events, support attribution; no calibrated PRF confidence is asserted.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. No claim of a separate SPOC pipeline is made. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Gaia orbit P=10.72678235 d. Representative photometric period 10.73037662 d; difference / Gaia quoted period error 1.05. Closest edge-on conjunction A: offset 0.612 d, covariance-linear error 0.457 d. Observed duration median 3.22 h; approximate central duration 8.06 h. These are feasibility diagnostics, not significance vetoes or a fitted geometry.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Signal class: target eclipsing binary; Gaia association: consistent within approximate orbit/geometry checks.

Execution: completed representative full review; scientific ambiguity: Gaia phase offset is 1.34 covariance-linear error units; grazing geometry can shorten the approximate central duration. No detailed physical fit or calibrated astrometric uncertainty.

Next deciding check: Characterize dilution and grazing geometry if needed.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all28 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C57. TIC 402940895 full report

Archived source: sanitized report text.

TIC 402940895: PLAUSIBLE

Queue position 40; batch04. Review by GPT-6.1 Sol with a fresh GPT-6.1 Terra helper, supervised by Astra. Physical classification and prior-catalogue status are separate.

Deciding assessment

Small sharp depressions lie on strong discontinuous sector 12/93 trends, while sector 103 flux is severely corrupted. Custom sector 12 fixed-shape depths 0.53/0.76% show features in the same photons, but their morphology is baseline sensitive and a stable eclipse sequence is unestablished.

Raw events and eclipse period

Two or three cached QLP SAP_FLUX sectors were checked with QUALITY=0. Representative events use local quadratic baselines plus trapezoid fits; TIC 60443793 instead uses the independently corrected alternating-minimum series, retained alongside the original search alias receipt. 5 representative fits were retained in raw-events.json, 5 clear of fit bounds. Depth range 0.0–0.674 percent. Period from representative event centers: not established as an eclipse period. Search-cycle counts are conditional on the initial search except where the corrected alternating-minimum receipt explicitly supersedes that alias. No timing uncertainty or ephemeris prediction is claimed.

Smooth-variable morphology is assessed in ambiguous-folds.json and helper receipts.

Source imaging and independent reduction

Sector 12 signed diagnostic has 2.79 arcsec Gaussian target offset, but strong baseline structure and lack of a clean independent later-sector event prevent secure source validation. Fresh sectors 12/103 were extracted.

Fresh TESScut cutouts are a distinct custom aperture reduction of the same TESS photons as QLP; they are not SPOC and do not supply an independent telescope. No claim of a separate SPOC pipeline is made. Signed in/out images use adjacent pre/post windows. Positive-clipped centroids and Gaussian formal errors are diagnostics subject to PRF mismatch; target-specific repeat tests and capable-neighbour comparisons govern attribution.

Gaia geometry

Gaia orbit P=16.44813821 d. No secure eclipse period exists for a meaningful conjunction/duration validation.

Computed receipt: gaia-geometry.json. Linear covariance propagation uses SB1 correlation order P,gamma,K1,e,omega,Tp; conjunction uses edge-on approximation. The mass-function/MS-radius duration is a feasibility estimate, not a physical fit. Circular/low-eccentricity periastron phases may be

weakly constrained.

Prior EB coverage

no identified prior EB; seven-scope coverage complete: yes. Reused central coverage-matrix.csv and catalogue-scope.json: VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* or ROT alone are not EB identifications. This scoped result is not an exhaustive discovery claim.

Completion, limitations and next check

Signal class: uncertain variability; Gaia association: not established.

Execution: completed representative full review; scientific ambiguity: Baseline/discontinuity sensitivity, corrupted sector 103, no secure eclipse period or repeated source validation.

Next deciding check: Re-extract clean sectors with robust background/pointing treatment before asserting eclipses.

Provenance: cache-manifest.json preserves original cached FITS paths and SHA256; identity-checks.json matches TICID/SECTOR for all28 input QLP files. tesscut-downloads.json records fresh source URLs and zip hashes; signed images and helper evidence have hashes. manifest.json records deliverable checksums. Adapted scripts are retained. No source-paper edits or publication performed.

C58. TIC 183994341 full report

Archived source: sanitized report text.

TIC 183994341: CONFIRMED

Queue position 41; batch05. Automated GPT-6.1 Sol lead and independent fresh GPT-6.1 Terra review, supervised by Astra. The anonymous project coordinator supplied oversight; these are computational measurements, not human measurements.

Assessment

Four repeated primary eclipses with raw depths25–29percent are on target and recovered independently. The eclipse period is approximately14.6655d; the ASAS-SN catalogue lists an incompatible2.9324d alias. The target is a known prior EB and excluded from new additions.

Raw repetition and period

Accepted target eclipse period: 14.665514216226159 days. 2 representative cached QLP sectors were reviewed using SAP_FLUX and QUALITY=0. Original packet periods were treated as candidate aliases. Corrected event fits use local linear baselines and trapezoids on raw cadences; no exhaustive sector fit or physical binary model was required.

{ "period_d": 14.665514216226159, "epoch_btjd": 3781.92483432609, "n_events": 4, "note": "Representative local event timing regression for939/183; direct consecutive event interval for431/222; no formal period error." }

Source and independent reduction

Sectors91/92 free Gaussian offsets1.71/1.58arcsec favor the target; closest capable neighbours38arcsec or farther give substantially worse fixed-source residuals (ratios22.8–44.1). Independent custom apertures reproduce repeated eclipses.

Fresh 11x11 TESScuts and 60 arcsec TIC source cones were obtained. Signed in/out images compare local pre/post baselines. The source model includes signed pixel-integrated Gaussians and fixed source positions with free widths/amplitude/background. Residual ratios are descriptive and do not constitute calibrated PRF probabilities. Neighbours capable under a conservative brightness/depth limit were compared; throughput, uncatalogued sources and TIC photometry remain limitations.

The independent custom target aperture subtracts a per-cadence background from faint cutout pixels and uses the same TESS photons as QLP. It is a distinct extraction, not SPOC or a second telescope. Terra independently inspected raw/custom comparison and signed images; quantitative four-EB depths and receipts are in raw-evidence/terra-helper-results.json. See HELPER.md, all-raw.png, raw-event-panels.png and terra-independent-comparison.png.

Gaia geometry and association

Four-event regression P14.665514216d versus Gaia14.670950076+/-0.003882078d. Approximate conjunction offset1.81d with propagated covariance0.93d and conservative absolute-sum1.76d; duration16.18h versus approximate central23.03h is physically feasible. The period, propagated approximate phase and duration are compatible with the Gaia orbit at current precision; the roughly1.9sigma phase difference alone is not a physical veto.

Association flag: compatible at approximate current precision; phase uncertainty retained.

The gaia-geometry.json calculation uses edge-on conjunctions, Tp+389 BTJD conversion, full SB1 covariance in P,gamma,K1,e,omega,Tp order, and linear propagation. Approximate mass function, TIC radius and main-sequence companion radius test feasibility, not a fitted geometry. No automatic Gaia sigma veto was applied.

Catalogue coverage

known prior EB; seven-scope coverage complete: yes. Central coverage includes VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, vetted Kostov2025 tables3/4 and ASAS-SN. SB* and ROT alone do not count as known EB. This scoped result is separate from physical assessment. TIC183994341 is known and excluded from new additions regardless of physical tier.

Completion, limits and next check

Full representative review complete; remaining full review=false. Available deciding checks were attempted. Scientific uncertainty: Real repeated on-target known EB. Approximate Gaia conjunction phase and radii limit characterization. Catalogue period conflict is retained rather than forcing catalogue cycles. No new-discovery claim.

Next check: Resolve ASAS-SN period alias and obtain RV/orbital posterior or a joint timing/geometry analysis to settle the Gaia association.

Provenance: raw-evidence/cache-manifest.json hashes the cached original QLP files; identity-checks.json verifies TICID/sector. Fresh TESScut URLs/SHA256 are in tesscut-downloads.json; source cones and adapted scripts are retained. manifest.json hashes batch deliverables. No paper edits, source table edits, publication or commits were made.

C59. TIC 166781582 full report

Archived source: sanitized report text.

TIC 166781582: PLAUSIBLE

Queue position 42; batch05. Automated GPT-6.1 Sol lead and independent fresh GPT-6.1 Terra review, supervised by Astra. The anonymous project coordinator supplied oversight; these are computational measurements, not human measurements.

Assessment

Broad smooth multi-day minima vary in shape and amplitude between sectors15/75/83. The long screen interval does not isolate discrete ingress/egress. The original candidate remains scientifically unestablished after the available representative checks.

Raw repetition and period

Accepted target eclipse period: not established days. 3 representative cached QLP sectors were reviewed using SAP_FLUX and QUALITY=0. Original packet periods were treated as candidate aliases. Corrected event fits use local linear baselines and trapezoids on raw cadences; no exhaustive sector fit or physical binary model was required.

{ "accepted_target_ephemeris": null, "reason": "No established target repeated eclipse; original alias fitter is not accepted evidence" }

Representative accepted event measurements:

[]

Source and independent reduction

Fresh TESScuts and target-centred custom apertures were inspected. Without a verified eclipse, a signed image at an arbitrary trial minimum cannot establish an eclipse host.

Fresh 11x11 TESScuts and 60 arcsec TIC source cones were obtained. Signed in/out images compare local pre/post baselines. The source model includes signed pixel-integrated Gaussians and fixed source positions with free widths/amplitude/background. Residual ratios are descriptive and do not constitute calibrated PRF probabilities. The independent custom target aperture subtracts a per-cadence background from faint cutout pixels and uses the same TESS photons as QLP. It is a distinct extraction, not SPOC or a second telescope. Terra independently inspected raw/custom comparison and signed images; quantitative four-EB depths and receipts are in raw-evidence/terra-helper-results.json. See HELPER.md, all-raw.png, raw-event-panels.png and terra-independent-comparison.png.

Gaia geometry and association

No eclipse-derived orbital period is established, so a Gaia-conjunction match cannot be claimed.

Association flag: unestablished.

The gaia-geometry.json calculation uses edge-on conjunctions, Tp+389 BTJD conversion, full SB1 covariance in P,gamma,K1,e,omega,Tp order, and linear propagation. Approximate mass function, TIC radius and main-sequence companion radius test feasibility, not a fitted geometry. No automatic Gaia sigma veto was applied.

Catalogue coverage

no identified prior EB; seven-scope coverage complete: yes. Central coverage includes VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, vetted Kostov2025 tables3/4 and ASAS-SN. SB* and ROT alone do not count as known EB. This scoped result is separate from physical assessment. TIC183994341 is known and excluded from new additions regardless of physical tier.

Completion, limits and next check

Full representative review complete; remaining full review=false. Available deciding checks were attempted. Scientific uncertainty: Full representative review completed; the candidate lacks established repeated eclipses. This does not exclude shallower eclipses or events outside the inspected sectors.

Next check: Obtain or inspect another clean sector and require repeated discrete ingress/egress before fitting a binary period.

Provenance: raw-evidence/cache-manifest.json hashes the cached original QLP files; identity-checks.json verifies TICID/sector. Fresh TESScut URLs/SHA256 are in tesscut-downloads.json; source cones and adapted scripts are retained. manifest.json hashes batch deliverables. No paper edits, source table edits, publication or commits were made.

C62. TIC 431762229 full report

Archived source: sanitized report text.

TIC 431762229: REFUTED

Queue position 45; batch05. Automated GPT-6.1 Sol lead and independent fresh GPT-6.1 Terra review, supervised by Astra. The anonymous project coordinator supplied oversight; these are computational measurements, not human measurements.

Assessment

Repeated real eclipses contaminate the target aperture, but are spatially associated with TIC431762222, separated32.79arcsec. REFUTED applies to target attribution and the original Gaia-period eclipse interpretation.

Raw repetition and period

Accepted target eclipse period: not established days. 3 representative cached QLP sectors were reviewed using SAP_FLUX and QUALITY=0. Original packet periods were treated as candidate aliases. Corrected event fits use local linear baselines and trapezoids on raw cadences; no exhaustive sector fit or physical binary model was required.

{ "accepted_target_ephemeris": null, "reason": "No established target repeated eclipse; original alias fitter is not accepted evidence" }

Representative accepted event measurements:

[]

Source and independent reduction

Two fresh detector-sector difference stacks repeatedly favor TIC431762222; fixed neighbour/target residual SSE ratios are0.0090/0.0188. Free Gaussian deficits lie close to that neighbour. The ratios are descriptive, not calibrated probabilities.

Fresh 11x11 TESScuts and 60 arcsec TIC source cones were obtained. Signed in/out images compare local pre/post baselines. The source model includes signed pixel-integrated Gaussians and fixed source positions with free widths/amplitude/background. Residual ratios are descriptive and do not constitute calibrated PRF probabilities. Neighbours capable under a conservative brightness/depth limit were compared; throughput, uncatalogued sources and TIC photometry remain limitations.

The independent custom target aperture subtracts a per-cadence background from faint cutout pixels and uses the same TESS photons as QLP. It is a distinct extraction, not SPOC or a second telescope. Terra independently inspected raw/custom comparison and signed images; quantitative four-EB depths and receipts are in raw-evidence/terra-helper-results.json. See HELPER.md, all-raw.png, raw-event-panels.png and terra-independent-comparison.png.

Gaia geometry and association

The contaminating eclipse interval isapproximately1.94d; the original screen alias is rejected as a target eclipse period. No target Gaia orbit association is inferred.

Association flag: contaminating neighbour.

The gaia-geometry.json calculation uses edge-on conjunctions, Tp+389 BTJD conversion, full SB1 covariance in P,gamma,K1,e,omega,Tp order, and linear propagation. Approximate mass function, TIC radius and main-sequence companion radius test feasibility, not a fitted geometry. No automatic Gaia sigma veto was applied.

Catalogue coverage

no identified prior EB; seven-scope coverage complete: yes. Central coverage includes VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, vetted Kostov2025 tables3/4 and ASAS-SN. SB* and ROT alone do not count as known EB. This scoped result is separate from physical assessment. TIC183994341 is known and excluded from new additions regardless of physical tier.

Completion, limits and next check

Full representative review complete; remaining full review=false. Available deciding checks were attempted. Scientific uncertainty: The contaminant is an inferred EB host; its catalogue novelty and precision binary orbit were not independently adjudicated. Source model systematics remain.

Next check: Higher resolution eclipse photometry can verify the contaminating host.

Provenance: raw-evidence/cache-manifest.json hashes the cached original QLP files; identity-checks.json verifies TICID/sector. Fresh TESScut URLs/SHA256 are in tesscut-downloads.json; source cones and adapted scripts are retained. manifest.json hashes batch deliverables. No paper edits, source table edits, publication or commits were made.

C63. TIC 350661747 full report

Archived source: sanitized report text.

TIC 350661747: PLAUSIBLE

Queue position 46; batch05. Automated GPT-6.1 Sol lead and independent fresh GPT-6.1 Terra review, supervised by Astra. The anonymous project coordinator supplied oversight; these are computational measurements, not human measurements.

Assessment

QLP sectors12/39/103 show large irregular trends; the giant sector103 changes are largely absent in the independent aperture. The trial deficit is displaced and is not an established eclipse. The original candidate remains scientifically unestablished after the available representative checks.

Raw repetition and period

Accepted target eclipse period: not established days. 3 representative cached QLP sectors were reviewed using SAP_FLUX and QUALITY=0. Original packet periods were treated as candidate aliases. Corrected event fits use local linear baselines and trapezoids on raw cadences; no exhaustive sector fit or physical binary model was required.

{ "accepted_target_ephemeris": null, "reason": "No established target repeated eclipse; original alias fitter is not accepted evidence" }

Representative accepted event measurements:

[]

Source and independent reduction

Fresh TESScuts and target-centred custom apertures were inspected. Without a verified eclipse, a signed image at an arbitrary trial minimum cannot establish an eclipse host.

Fresh 11x11 TESScuts and 60 arcsec TIC source cones were obtained. Signed in/out images compare local pre/post baselines. The source model includes signed pixel-integrated Gaussians and fixed source positions with free widths/amplitude/background. See HELPER.md, all-raw.png, raw-event-panels.png and terra-independent-comparison.png.

Gaia geometry and association

The screen period17.329d is not derived from accepted eclipse events. No Gaia eclipse association is established.

Association flag: screen artifact.

The gaia-geometry.json calculation uses edge-on conjunctions, Tp+389 BTJD conversion, full SB1 covariance in P,gamma,K1,e,omega,Tp order, and linear propagation. Approximate mass function, TIC radius and main-sequence companion radius test feasibility, not a fitted geometry. No automatic Gaia sigma veto was applied.

Catalogue coverage

no identified prior EB; seven-scope coverage complete: yes. Central coverage includes VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, vetted Kostov2025 tables3/4 and ASAS-SN. SB* and ROT alone do not count as known EB. This scoped result is separate from physical assessment. TIC183994341 is known and excluded from new additions regardless of physical tier.

Completion, limits and next check

Full representative review complete; remaining full review=false. Available deciding checks were attempted. Scientific uncertainty: REFUTED applies to the proposed deep-eclipse interpretation of the measured screen signal. Shallower unrelated variability is not excluded.

Next check: If revisiting, use clean cadences away from downlink boundaries with a validated background and aperture.

Provenance: raw-evidence/cache-manifest.json hashes the cached original QLP files; identity-checks.json verifies TICID/sector. Fresh TESScut URLs/SHA256 are in tesscut-downloads.json; source cones and adapted scripts are retained. manifest.json hashes batch deliverables. No paper edits, source table edits, publication or commits were made.

C67. TIC 9396327 full report

Archived source: sanitized report text.

TIC 9396327: PROBABLE

Queue position 50; batch05. Automated GPT-6.1 Sol lead and independent fresh GPT-6.1 Terra review, supervised by Astra. The anonymous project coordinator supplied oversight; these are computational measurements, not human measurements.

Assessment

Six fully covered primary events repeat in raw flux with depth28–29percent and consistent discrete morphology. Independent aperture reduction reproduces the events and the signed deficit favors the target. The Gaia-orbit geometry check remains unresolved.

Raw repetition and period

Accepted target eclipse period: 2.4416706861122432 days. 1 representative cached QLP sectors were reviewed using SAP_FLUX and QUALITY=0. Original packet periods were treated as candidate aliases. Corrected event fits use local linear baselines and trapezoids on raw cadences; no exhaustive sector fit or physical binary model was required.

Source and independent reduction

Sector80 free Gaussian deficit lies0.56arcsec from target. Capable TIC neighbours51.4/55.9arcsec away have fixed neighbour/target SSE ratios74.9/70.5, strongly worse descriptively. The independent custom aperture reproduces repeated eclipses.

Fresh 11x11 TESScuts and 60 arcsec TIC source cones were obtained. Signed in/out images compare local pre/post baselines. The source model includes signed pixel-integrated Gaussians and fixed source positions with free widths/amplitude/background. Residual ratios are descriptive and do not constitute calibrated PRF probabilities. Neighbours capable under a conservative brightness/depth limit were compared; throughput, uncatalogued sources and TIC photometry remain limitations.

The independent custom target aperture subtracts a per-cadence background from faint cutout pixels and uses the same TESS photons as QLP. It is a distinct extraction, not SPOC or a second telescope. Terra independently inspected raw/custom comparison and signed images; quantitative four-EB depths

and receipts are in raw-evidence/terra-helper-results.json. See HELPER.md, all-raw.png, raw-event-panels.png and terra-independent-comparison.png.

Gaia geometry and association

Representative six-event regression gives2.441670686d (timing residuals below0.00056d); Gaia2.441934355+/-0.000085226d. A sector-end partial event was excluded because its distorted timing shifts the inferred period. Approximate conjunction A offset0.347d versus propagated covariance0.116d; period differences alone do not veto an EB. Duration3.36h is feasible relative to central4.81h. Secondary-event phase and propagated orbital phase prevent claiming a fully consistent Gaia association.

Association flag: unresolved; no firm by-catch.

The gaia-geometry.json calculation uses edge-on conjunctions, Tp+389 BTJD conversion, full SB1 covariance in P,gamma,K1,e,omega,Tp order, and linear propagation. Approximate mass function, TIC radius and main-sequence companion radius test feasibility, not a fitted geometry. No automatic Gaia sigma veto was applied.

Catalogue coverage

no identified prior EB; seven-scope coverage complete: yes. Central coverage includes VSX, SIMBAD primary type, Gaia DR3 EB, Prsa2022, IJspeert2024, vetted Kostov2025 tables3/4 and ASAS-SN. SB* and ROT alone do not count as known EB. This scoped result is separate from physical assessment. TIC183994341 is known and excluded from new additions regardless of physical tier.

Completion, limits and next check

Full representative review complete; remaining full review=false. Available deciding checks were attempted. Scientific uncertainty: Real on-target repeating EB; PROBABLE because the Gaia geometry/association check is unresolved. One fresh detector sector only; same-photon independent reduction. No firm by-catch flag: a modest period mismatch does not establish a separate orbit.

Next check: Refine Gaia conjunction predictions with orbital posterior and measure a second clean sector or obtain new RVs to test the orbit association.

Provenance: raw-evidence/cache-manifest.json hashes the cached original QLP files; identity-checks.json verifies TICID/sector. Fresh TESScut URLs/SHA256 are in tesscut-downloads.json; source cones and adapted scripts are retained. manifest.json hashes batch deliverables. No paper edits, source table edits, publication or commits were made.

C68. TIC 275022619 full report

Archived source: sanitized report text.

TIC 275022619: PLAUSIBLE

Queue position 51; batch06. Review credits: GPT-6.1 Sol, fresh GPT-6.1 Terra review, supervised by Astra. This is AI review, not human validation.

1. Raw morphology and repeat assessment

QLP sectors 12,65,103 show smooth slopes and broad variability. The sharp-looking sector103 changes occur at segment edges. At the covered original nominal phase, the short-window signed depth is negative (brightening), and the template fit hits its timing/duration bounds. The fresh custom aperture shows smooth variability and segment offsets without a repeat narrow eclipse. Independent Terra audit retains PLAUSIBLE: the available representative data fail to establish recurring eclipses, but sparse/compromised coverage does not tie the original search detection to a specific demonstrated artifact. This is not a secure eclipse identification.

Three cached QLP SAP_FLUX FITS sectors were checked with QUALITY=0 and target/sector header verification. Local quadratic baseline plus trapezoid fits are in raw-events.json, including failed or boundary fits. No non-boundary fit exceeds three local residual RMS; no repeat eclipse series establishes a period. Original search period 17.575404492 d is retained only as a conditional alias, not a derived ephemeris. The full morphology overview explicitly checks features away from that alias; raw-event fits alone do not decide the result. Covered conditional phases: [{"sector": 103, "cycle": 143, "nominal_tc": 4153.2634422981155, "n_in": 68, "n_pre": 113, "n_post": 113, "covered": true, "signed_depth": -0.012590765953063965, "local_rms": 0.027302270755171776}].

2. Source and independent reduction

Fresh 11x11 TESScut images and TIC 60-arcsec cones were obtained in two sectors. Signed candidate-phase difference images and fixed-coordinate target/capable-neighbour comparisons were attempted using the original search phase. Since no real repeating eclipse exists to localize, these candidate-only fits do not establish an eclipse host or an off-target EB. They are retained as failed candidate tests, not localization detections. Capability limits use the original claimed depth and ignore aperture throughput/bandpass uncertainty.

Fresh cutout sectors: 65,103. Candidate capability counts: 65: 19,103: 19. Source comparisons are descriptive signed-image Gaussian fits, with no calibrated PRF confidence. Neighbour catalogue identity can include unresolved or duplicate records. The independent extraction subtracts each frame's lowest-30-pixel median background then sums a central 3x3 aperture, with QUALITY=0. It uses the same TESS photons through a distinct reduction, and is not SPOC. custom-morphology.png and custom-extraction.json preserve its deciding morphology.

3. Gaia orbit

Gaia NSS orbit metadata were inspected, but no photometric eclipse ephemeris was established; an eclipse/conjunction geometry comparison is therefore inapplicable. Nearness of the original search alias to the Gaia period cannot establish eclipses.

Gaia source 5984329116365907584; NSS P=17.538395407 +/- 0.010265369 d; e=0.05981, omega=247.3903 degrees. No eclipse timing or geometry is inferred from this metadata. No photometric eclipse orbit established; Gaia spectroscopic binarity not refuted.

4. Scoped prior EB coverage

no identified prior EB; coverage complete: yes. Reused centrally completed seven scopes: VSX, SIMBAD primary type, Gaia DR3 eclipsing binaries, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* and ROT alone are not EB identifications; Kostov table2 is unvetted. This is a scoped catalogue result, not an exhaustive discovery claim. Physical and novelty verdicts are separate.

5. Completion and limitations

The representative full review is complete. Scientific outcome: eclipse morphology and repetition remain unresolved; this is not a secure eclipse identification. Missing eclipse geometry reflects the absence of a valid eclipse series, not unfinished execution. Representative three QLP sectors and two independent custom-extraction sectors; no exhaustive all-sector search, calibrated PRF/noise model, physical fit or sensitivity upper limit. No secure eclipse identification or exclusion of all possible shallow eclipses follows. Repetition and eclipse morphology remain scientifically uncertain; no calibrated sensitivity or propagated ephemeris-error analysis was performed.

Next check: Obtain a well-covered predicted candidate event in a distinct reduction and establish a second coherent detached eclipse before claiming an eclipse period or host.

Provenance: raw-evidence/cache-manifest.json preserves original cache paths and SHA256; identity-checks.json verifies all 15 QLP inputs; tesscut-downloads.json stores fresh URLs and zip hashes; TIC raw cones and adapted scripts are retained. manifest.json hashes deliverables. No paper edits, commits or publication were performed.

C69. TIC 297541839 full report

Queue position 52; batch06. Review credits: GPT-6.1 Sol, fresh GPT-6.1 Terra review, supervised by Astra. This is AI review, not human validation.

1. Raw morphology and repeat assessment

QLP sectors11,64,100 show broad smooth variable minima rather than short eclipses. Covered nominal candidate phases have short-window depths only 0.100,0.077,0.017 percent, versus the original search depth 0.533 percent, and fits have depths smaller than local residual scatter. The distinct fresh custom aperture also shows smooth variability and segment offsets without recurring detached eclipses.

Three cached QLP SAP_FLUX FITS sectors were checked with QUALITY=0 and target/sector header verification. Local quadratic baseline plus trapezoid fits are in raw-events.json, including failed or boundary fits. No non-boundary fit exceeds three local residual RMS; no repeat eclipse series establishes a period. Original search period 16.363592725 d is retained only as a conditional alias, not a derived ephemeris. The full morphology overview explicitly checks features away from that alias; raw-event fits alone do not decide the result. Covered conditional phases: [{"sector": 11, "cycle": 0, "nominal_tc": 1601.1092, "n_in": 4, "n_pre": 5, "n_post": 6, "covered": true, "signed_depth": 0.0010014176368713379, "local_rms": 0.001233667484484613}, {"sector": 64, "cycle": 89, "nominal_tc": 3057.468952514513, "n_in": 31, "n_pre": 52, "n_post": 52, "covered": true, "signed_depth": 0.0007699728012084961, "local_rms": 0.0038203957956284285}, {"sector": 100, "cycle": 152, "nominal_tc": 4088.3752941820903, "n_in": 31, "n_pre": 52, "n_post": 52, "covered": true, "signed_depth": 0.00016689300537109375, "local_rms": 0.00291615072637796 4}].

2. Source and independent reduction

Fresh 11x11 TESScut images and TIC 60-arcsec cones were obtained in two sectors. Signed candidate-phase difference images and fixed-coordinate target/capable-neighbour comparisons were attempted using the original search phase. Since no real repeating eclipse exists to localize, these candidate-only fits do not establish an eclipse host or an off-target EB. They are retained as failed candidate tests, not localization detections. Capability limits use the original claimed depth and ignore aperture throughput/bandpass uncertainty.

Fresh cutout sectors: 64,100. Candidate capability counts: 64: 23,100: 23. Source comparisons are descriptive signed-image Gaussian fits, with no calibrated PRF confidence. Neighbour catalogue identity can include unresolved or duplicate records. The independent extraction subtracts each frame's lowest-30-pixel median background then sums a central 3x3 aperture, with QUALITY=0. It uses the same TESS photons through a distinct reduction, and is not SPOC. custom-morphology.png and custom-extraction.json preserve its deciding morphology.

3. Gaia orbit

Gaia NSS orbit metadata were inspected, but no photometric eclipse ephemeris was established; an eclipse/conjunction geometry comparison is therefore inapplicable. Nearness of the original search alias to the Gaia period cannot establish eclipses.

Gaia source 5854775658438572416; NSS P=16.417997076 +/- 0.013138885 d; e=0.02946, omega=13.3971 degrees. No eclipse timing or geometry is inferred from this metadata. No photometric eclipse orbit established; Gaia spectroscopic binarity not refuted.

4. Scoped prior EB coverage

no identified prior EB; coverage complete: yes. Reused centrally completed seven scopes: VSX, SIMBAD primary type, Gaia DR3 eclipsing binaries, Prsa2022, IJspeert2024, Kostov2025 vetted tables3/4, ASAS-SN. SB* and ROT alone are not EB identifications; Kostov table2 is unvetted. This is a scoped catalogue result, not an exhaustive discovery claim. Physical and novelty verdicts are separate.

5. Completion and limitations

The representative full review is complete. Scientific outcome: submitted eclipse interpretation refuted by a demonstrated smooth/systematic explanation. Missing eclipse geometry reflects the absence of a valid eclipse series, not unfinished execution. Representative three QLP sectors and two independent custom-extraction sectors; no exhaustive all-sector search, calibrated PRF/noise model, physical fit or sensitivity upper limit. Refutation applies to the submitted eclipse interpretation, not to binarity or all possible shallow eclipses.

Next check: No missing deciding gate for this candidate. Reopen only if new data supply distinct, repeated detached events.

Provenance: raw-evidence/cache-manifest.json preserves original cache paths and SHA256; identity-checks.json verifies all 15 QLP inputs; tesscut-downloads.json stores fresh URLs and zip hashes; TIC raw cones and adapted scripts are retained. manifest.json hashes deliverables. TIC 396248369: REFUTED

Queue position 53; batch06. Review credits: GPT-6.1 Sol, fresh GPT-6.1 Terra review, supervised by Astra. This is AI review, not human validation.

1. Raw morphology and repeat assessment

QLP sectors13,94,103 include apparent sharp dips near rapid baseline changes, but the original-phase fits fail to establish real repeat eclipses. In the fresh custom extraction, the S94/S103 apparent dips correspond to large positive ramps or segment-level changes; a detached negative eclipse is not independently recovered. Original covered phases have sub-millimagnitude or negative short-window signed deficits. The search period is not a measured binary eclipse period.

Three cached QLP SAP_FLUX FITS sectors were checked with QUALITY=0 and target/sector header verification. Local quadratic baseline plus trapezoid fits are in raw-events.json, including failed or boundary fits. No non-boundary fit exceeds three local residual RMS; no repeat eclipse series establishes a period. Original search period 18.390769704 d is retained only as a conditional alias, not a derived ephemeris. The full morphology overview explicitly checks features away from that alias; raw-event fits alone do not decide the result. Covered conditional phases: [{"sector": 13, "cycle": 0, "nominal_tc": 1663.3432, "n_in": 4, "n_pre": 8, "n_post": 8, "covered": true, "signed_depth": -0.0002053380012512207, "local_rms": 0.0014788307016715407}, {"sector": 13, "cycle": 1, "nominal_tc": 1681.7339697044129, "n_in": 6, "n_pre": 9, "n_post": 8, "covered": true, "signed_depth": 0.0006639957427978516, "local_rms": 0.000878628867212683}, {"sector": 94, "cycle": 120, "nominal_tc": 3870.23556452954, "n_in": 46, "n_pre": 78, "n_post": 78, "covered": true, "signed_depth": 0.00036269426345825195, "local_rms": 0.005096118431538343}, {"sector": 103, "cycle": 136, "nominal_tc": 4164.4878798001455, "n_in": 40, "n_pre": 69, "n_post": 51, "covered": true, "signed_depth": -0.0019028186798095703, "local_rms": 0.028664467856287956}].

2. Source and independent reduction

Fresh 11x11 TESScut images and TIC 60-arcsec cones were obtained in two sectors. Signed candidate-phase difference images and fixed-coordinate target/capable-neighbour comparisons were attempted using the original search phase. Since no real repeating eclipse exists to localize, these candidate-only fits do not establish an eclipse host or an off-target EB. They are retained as failed candidate tests, not localization detections. Capability limits use the original claimed depth and ignore aperture throughput/bandpass uncertainty.

Archived source: sanitized report text.

TIC 277479128: REFUTED

Queue position 54; batch06. Review credits: GPT-6.1 Sol, fresh GPT-6.1 Terra review, supervised by Astra. This is AI review, not human validation.

1. Raw morphology and repeat assessment

QLP sectors 13,92,94 contain broad multi-day variability and large segment changes. The sharp-looking S94 minimum is a distorted edge on broad variability: the distinct fresh aperture shows a multi-day minimum rather than a short detached eclipse. Covered nominal phases have negative short-window signed deficits; the strong S94 template fit hits its timing bound. No repeating detached event establishes an eclipse period.

Three cached QLP SAP_FLUX FITS sectors were checked with QUALITY=0 and target/sector header verification. Local quadratic baseline plus trapezoid fits are in raw-events.json, including failed or boundary fits. No non-boundary fit exceeds three local residual RMS; no repeat eclipse series establishes a period. Original search period 19.667413548 d is retained only as a conditional alias, not a derived ephemeris. The full morphology overview explicitly checks features away from that alias; raw-event fits alone do not decide the result. Covered conditional phases: [{"sector": 13, "cycle": 0, "nominal_tc": 1667.3914, "n_in": 7, "n_pre": 12, "n_post": 4, "covered": true, "signed_depth": -0.0013865232467651367, "local_rms": 0.005576646886765957}, {"sector": 92, "cycle": 109, "nominal_tc": 3811.139476703976, "n_in": 67, "n_pre": 113, "n_post": 113, "covered": true, "signed_depth": -0.000667572021484375, "local_rms": 0.004877484869211912}, {"sector": 94, "cycle": 112, "nominal_tc": 3870.1417173472046, "n_in": 67, "n_pre": 113, "n_post": 113, "covered": true, "signed_depth": -0.04576444625854492, "local_rms": 0.07903945446014404}].

C72. TIC 257575960 full report

Archived source: sanitized report text.

TIC 257575960: PLAUSIBLE

Queue position 55; batch06. Review credits: GPT-6.1 Sol, fresh GPT-6.1 Terra review, supervised by Astra. This is AI review, not human validation.

1. Raw morphology and repeat assessment

QLP sectors 12,67,102 show orbit-segment ramps, noisy low-amplitude variation and repeated plateaus/steps. Original nominal phases in sectors12/67 have no coherent short eclipse; fitted positive depths are below local residual scatter. The fresh independent aperture reproduces the sector102 segment plateaus/steps and noisy S67 curve without detached recurring dips. Independent Terra audit retains PLAUSIBLE: the available representative data fail to establish recurring eclipses, but sparse/compromised coverage does not tie the original search detection to a specific demonstrated artifact. This is not a secure eclipse identification.

Three cached QLP SAP_FLUX FITS sectors were checked with QUALITY=0 and target/sector header verification. Local quadratic baseline plus trapezoid fits are in raw-events.json, including failed or boundary fits. No non-boundary fit exceeds three local residual RMS; no repeat eclipse series establishes a period. Original search period 13.410727098 d is retained only as a conditional alias, not a derived ephemeris. The full morphology overview explicitly checks features away from that alias; raw-event fits alone do not decide the result. Covered conditional phases: [{"sector": 12, "cycle": 1, "nominal_tc": 1644.6230270979095, "n_in": 8, "n_pre": 12, "n_post": 13, "covered": true, "signed_depth": -0.00010025501251220703, "local_rms": 0.0011402764357626438}, {"sector": 67, "cycle": 113, "nominal_tc": 3146.624462063768, "n_in": 48, "n_pre": 108, "n_post": 71, "covered": true, "signed_depth": -0.0006230473518371582, "local_rms": 0.003330210456624627}].

period_origin: eclipse timing

period_error_kind: source-specific formal timing error with stated floors/scatter

reference_epoch_btjd: 2818.48299

epoch_kind: A

depth_ppt: 44.1

novelty_status: no identified prior EB in seven scoped groups

limitations: Only two A eclipses; no internal timing residual test. B windows are contaminated or missing; no B detection. Gaia conjunction uncertainty is 3-4 d.

next_check: Observe a third A eclipse and a clean B window near 0.3% precision.

Current full report and deciding evidence

P018. TIC 64066759 - CONFIRMED

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 40.93770552812586

period_error_days: 4.02430562196e-05

period_origin: eclipse timing

period_error_kind: source-specific formal timing error with stated floors/scatter

reference_epoch_btjd: 3674.520856303387

epoch_kind: A

depth_ppt: 22.0

novelty_status: no identified prior EB in seven scoped groups

limitations: Long-baseline precision partly depends on a fixed-shape partial s7 event; three events total. Simplified geometry favours smaller primary radius than TIC. No B expected.

next_check: Fit a full limb-darkened joint A model and constrain primary radius spectroscopically.

Current full report and deciding evidence

P019. TIC 49416839 - CONFIRMED

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 21.428466564976848

period_error_days: 4.771732314e-05

period_origin: eclipse timing

period_error_kind: source-specific formal timing error with stated floors/scatter

reference_epoch_btjd: 1558.284949338288

epoch_kind: B (dominant deep eclipse)

depth_ppt: 13.3

novelty_status: no identified prior EB in seven scoped groups

limitations: A3 lacks egress and is weak. B-A phase separation is 2.3 sigma from Gaia; simple joint geometry has limited constraints. Dominant deep eclipse is labelled B in source.

next_check: Obtain a complete A event and joint free-eccentricity model to test the phase-separation tension.

Current full report and deciding evidence

P020. TIC 8853239 - PLAUSIBLE

count_addition: false

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 24.647

period_error_days: 0.0114

period_origin: Gaia SB1 only

period_error_kind: Gaia formal orbit error

reference_epoch_btjd: 2629.0699

epoch_kind: A; Gaia-only period

depth_ppt: 60.0

novelty_status: no identified prior EB in seven scoped groups

limitations: Single secure event; Gaia-only period; KELT null is coverage-limited and not a refutation. Tentative B is not an ephemeris.

next_check: Measure a second A eclipse to test the cycle period; a B detection alone would still need repeat timing.

Current full report and deciding evidence

P021. TIC 60583013 - CONFIRMED

count_addition: true

period_error_kind: source-specific formal timing error with stated floors/scatter

reference_epoch_btjd: 2210.9657

epoch_kind: A (period measured from B)

depth_ppt: 41.2

novelty_status: no identified prior EB in seven scoped groups

limitations: Period relies on two secondaries, one after a data gap; one primary only. Older B pixel test inconclusive. Duration geometry is approximate.

next_check: Obtain a second primary and joint limb-darkened model to test phase separation and geometry.

Current full report and deciding evidence

P022. TIC 277542587 - CONFIRMED

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 24.3318

period_error_days: 0.0002

period_origin: KELT+TESS; heuristic error

period_error_kind: heuristic working precision; not calibrated1sigma

reference_epoch_btjd: 3488.8242

epoch_kind: A; KELT+TESS period

depth_ppt: 77.6

novelty_status: no identified prior EB in seven scoped groups

limitations: TESS A mostly flagged; only one TESS A+B pair. KELT period precision is heuristic and anchored to TESS; broad ground aperture dilutes depth. Sparse KELT B is supporting only. Historical exact-night count not adopted.

next_check: Obtain another full well-calibrated A/B pair and an event-timing based period uncertainty.

Current full report and deciding evidence

P023. TIC 12864953 - CONFIRMED

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 31.632857663754894

period_error_days: 0.00015

period_origin: eclipse timing

period_error_kind: conservative timing allowance; not calibrated coverage

reference_epoch_btjd: 3204.1016

epoch_kind: A (period from repeated B)

depth_ppt: 17.24

novelty_status: no identified prior EB in seven scoped groups

limitations: Only two B events and one clean A; A ephemeris assumes B period. New A window is entirely quality 2048 flagged. Phase-separation tension about 3.35 sigma remains. Conservative period error is an estimate, not calibrated coverage.

next_check: Obtain a clean repeated A and refined radial-velocity orbit to resolve eccentricity/phase tension.

Current full report and deciding evidence

Underexplored selections: current measurements and evidence

The frozen magnitude-ordered period-fold queue and adaptive exploratory pilot use existing physical criteria. They have separate selection and attempted-data denominators; operational processing groups are not scientific methods. Full reports below retain deciding measurements and limitations. New timing periods are measured from eclipse midpoints, not predicted conjunction centers.

R175. TIC 300217120 - current measurements

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 14.158577492046303

reference_epoch_btjd: 2884.3381092475142

depth_ppt: 219.83441151981677

novelty_status: no identified prior EB

limitations: Deep repeated eclipses are isolated in both reductions; all four measured primary events support the timing solution.

next_check: Optional precision characterization

Full report and illustrated deciding evidence

R181. TIC 397586559 - current measurements

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 9.866288327778928

period_error_days: 2.7660310467344676e-05

reference_epoch_btjd: 2452.71248468518

depth_ppt: 253.71926940278945

novelty_status: no identified prior EB

limitations: Unequal alternating eclipses (primary median approximately254 ppt, secondary164 ppt) establish orbital period twice the historical4.93316d event spacing. Only deeper even cycles enter the reported primary ephemeris. Historical S70 difference image mixes both eclipse kinds, so its aperture depth is a mixture. Gaia nominal conjunction is0.28093d later at the TESS epoch; measured-Gaia period difference−0.00126495d accumulates this offset. Projecting toward the Gaia2016 reference reduces offset to−0.0166d; the orbit association is physically consistent with an imperfect Gaia period, and the tension is retained rather than subjected to a sigma veto.

next_check: Optional precision characterization

Full report and illustrated deciding evidence

R182. TIC 305801065 - current measurements

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 6.045029317589018

period_error_days: 3.61616161282754e-05

reference_epoch_btjd: 1727.4094898160802

depth_ppt: 5.0649222211815

novelty_status: no identified prior EB

limitations: The shallow eclipse is clearly repeated with localized ingress/egress despite higher scatter in newer sectors. Three capable neighbours at28.07,33.30,54.57arcsec are separated from the compact target deficit. Depth depends on dilution and trapezoid shape; historical median3.8ppt is not a precision intrinsic depth.

next_check: Optional precision characterization

Full report and illustrated deciding evidence

R183. TIC 345794632 - current measurements

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 14.644264849868913

period_error_days: 0.00019858296949633555

reference_epoch_btjd: 1716.285636447413

depth_ppt: 42.29190632036057

novelty_status: no identified prior EB

limitations: Five clean primary repeats determine the ephemeris. S76 historical cycle 154 has structured excursions and an anomalously weak fitted dip; S84 cycle 176 has a broad distorted profile. Both remain in raw-windows.csv and plots but are excluded from the timing fit. The capable neighbour at 55.00 arcsec is separated from the compact target deficit. Aperture and local baseline variations limit depth precision. The retained timing fit has reduced chi-square 18.08; residual timing scatter materially inflates the stated period error and shows model/baseline limitations.

next_check: Optional precision characterization

Full report and illustrated deciding evidence

R200. TIC 314041837 - current measurements

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 4.477995650988368

period_error_days: 1.534143438335759e-05

reference_epoch_btjd: 1770.0417342831945

depth_ppt: 44.521015368131536

novelty_status: no identified prior EB

limitations: The target is a large star (TIC radius 5.09 solar radii) with ellipsoidal modulation plus localized eclipses. A two-harmonic baseline fitted outside the primary core in S77 leaves a 30.31 ppt localized deficit; its double-wave modulation does not explain the eclipse. See harmonic-test.json and png. The 18.79 h local-linear trapezoid width includes smooth variability and is not a physical eclipse duration. The reported depth likewise describes that local model, not intrinsic eclipse depth. Capable neighbours at 27.40 and 53.17 arcsec are away from the target-centered deficit; PSF residual 0.595 limits morphology precision.

next_check: Optional precision characterization

Full report and illustrated deciding evidence

R201. TIC 7446763 - current measurements

count_addition: true

reference_epoch_btjd: 1843.6400352066814

depth_ppt: 140.88533223993306

novelty_status: no identified prior EB

limitations: A capable neighbour at 39.75 arcsec is separated from the target deficit. The target sits near a pixel boundary: the global deficit peak rounds to an adjacent pixel, while the centroid is only 3.64 arcsec from the actual target. This is not evidence for a different source.

next_check: Optional precision characterization

Full report and illustrated deciding evidence

R203. TIC 62940616 - current measurements

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 4.998587293904812

period_error_days: 1.3192060525370641e-05

reference_epoch_btjd: 2556.444026565471

depth_ppt: 52.59401180953602

novelty_status: no identified prior EB

limitations: One capable neighbour at 22.67 arcsec requires a 0.329 fractional eclipse to explain the signal, but the lost-light centroid lies 0.205 pixel from the target versus 1.33 pixels from that neighbour, displaced away from it. Its pixel fractional loss 0.0416 is a blended-pixel value and does not measure the neighbour intrinsic eclipse depth. The target-centered depth increases in the 1x1 aperture, consistent with target dilution in larger apertures. TESS resolution and G-to-TESS colour differences limit attribution precision.

depth_ppt: 84.03451128246843

novelty_status: no identified prior EB

limitations: Four clean primary events in S56 and S83 support the timing solution and approximately 84 ppt raw QLP depth. No capable neighbour is present in the 60 arcsec screen.

next_check: Optional precision characterization

Full report and illustrated deciding evidence

R205. TIC 77176486 - current measurements

count_addition: true

full_review_completion: COMPLETE_BOUNDED_REVIEW

period_days: 13.753691913407923

period_error_days: 1.89931259791415e-05

reference_epoch_btjd: 2153.315120594371

depth_ppt: 12.943912782527418

novelty_status: no identified prior EB

limitations: The 13.75369 d signal lies near the TESS orbital timescale, but repeated localized raw SAP dips in S31 and S98 and the target-centered cutout deficit support astrophysical eclipses. Quality-nonzero cadences are excluded; no flagged or uncovered window is a clean null. Cycle188 is visibly present but its trapezoid covariance is singular, so it is excluded from timing. Bounded S98 pixel/background check (background-check.json) finds target-pixel losses11.99/22.43/16.35 electrons/s versus3.24/9.85/7.73 at the close capable neighbour and0.70/6.30/3.36 at the farther one. Outer-pixel median losses are -0.027/5.68/4.04: common-mode background affects later events, while cycle187 is localized with negligible outer deficit. Core quality flags are0/0/3; flagged cadences are excluded. FLUX_BKG is zero throughout and supplies no independent background measurement. These are descriptive diagnostics, not a calibrated artifact veto. Gaia conjunction offset is 0.04208 phase with 0.549 d propagated uncertainty; this is association support with appreciable orbital uncertainty, not a precise phase coincidence.

period_error_days: 3.73397661927236e-06

reference_epoch_btjd: 2475.274686430569

depth_ppt: 48.52986342115804

novelty_status: no identified prior EB

limitations: QLP free-trapezoid depths show modest parity differences, especially in S71; local baseline and aperture dependence are material. Independent S43 3x3 cutout depths are 35.34-37.19 ppt for eight events including consecutive odd/even cycles, without a stable unequal alternating pattern. Gaia P=2.732167 d matches the measured event spacing. These data do not establish two distinct alternating eclipse kinds or require doubling; report the fitted period as the adopted orbit with this depth-model limitation, and the epoch as an observed reference eclipse. Capable neighbours at 35.19 and 35.89 arcsec are displaced from the compact target deficit.

next_check: Optional precision characterization

Full report and illustrated deciding evidence

R209. TIC 37948318 - current measurements

count_addition: true

reference_epoch_btjd: 1444.2226216138542

depth_ppt: 11.181622059581528

novelty_status: no identified prior EB

limitations: The historical absolute target-to-deficit offset is 15.1 arcsec (0.719 pixel), while light-to-deficit separation is 3.51 arcsec; these are distinct comparisons. The capable G13.73 neighbour is 53.65 arcsec away and opposite the deficit displacement. Independent per-event pixel checks find target-pixel losses 9.03-10.59 electrons/s against 0.185-0.437 at that neighbour in cycles317,319,321. This supports the target over the capable neighbour at TESS resolution, with an uncalibrated absolute-centroid systematic and residual crowding uncertainty. Historical cycles316/318 have common-mode excursions and are not individually decisive. QLP cycle93 has singular timing covariance and is excluded from timing.

next_check: Optional precision characterization

epoch_kind: B

depth_ppt: 104.05549881862092

novelty_status: known IJspeert2024 EB recovery; zero new-system addition

limitations: Pilot characterization; period errors are scatter-only. No exhaustive literature priority claim.

next_check: Optional precision characterization; no missing bounded admission check

Archived source: sanitized report text.

> Supervisor-accepted physical review: CONFIRMED. Known recovery; excluded from new-system count. Earlier pending-admission wording below records the original handoff.

TIC 155303130: CONFIRMED

Scientific method/population: fresh Gaia-conjunction appointments G11.5-12 P20-60d. Physical review completion: complete bounded first pass, independently audited in helper/AUDIT.md; supervisor admission pending. Catalogue novelty is separate: known IJspeert2024 EB recovery; zero new-system addition.

1. Repeated raw eclipses: PASS. 4 fit-eligible raw SAP events in sectors [71, 72, 87]. Trapezoid depths median 104.06 ppt; duration median 13.10 h. All saved events, rejected fits and raw files are identified in timing-results.json; no claim that other sectors are clean nulls. QUALITY==0 used. Existing raw observations were remeasured, not merely called eclipses from BLS.
2. Eclipse timing: PASS. P=20.5247770157 d; B-eclipse reference epoch BTJD 3238.19605357; OLS scatter SE 0.000337625627 d; residual RMS 5.974 min. This SE excludes cadence/template/extraction systematics and is not calibrated coverage. Fits are representative, not all-event precision ephemerides.
3. Target pixels: PASS. Sector 71, 2 event stack, peak pixel [7, 8] equals target [7, 8]; centroid-target 1.51 arcsec. 1 distinct Gaia neighbours could supply the flux under the conservative total-flux bound. The marginally capable neighbour at32.394arcsec is spatially distinct from the1.51arcsec target-centered deficit; it is not discarded merely because it is faint. Catalogue incompleteness/unresolved companions are not excluded. Gaia position used consistently with target ID. The older diffstack n_possible field includes the target itself; this report explicitly removes it.

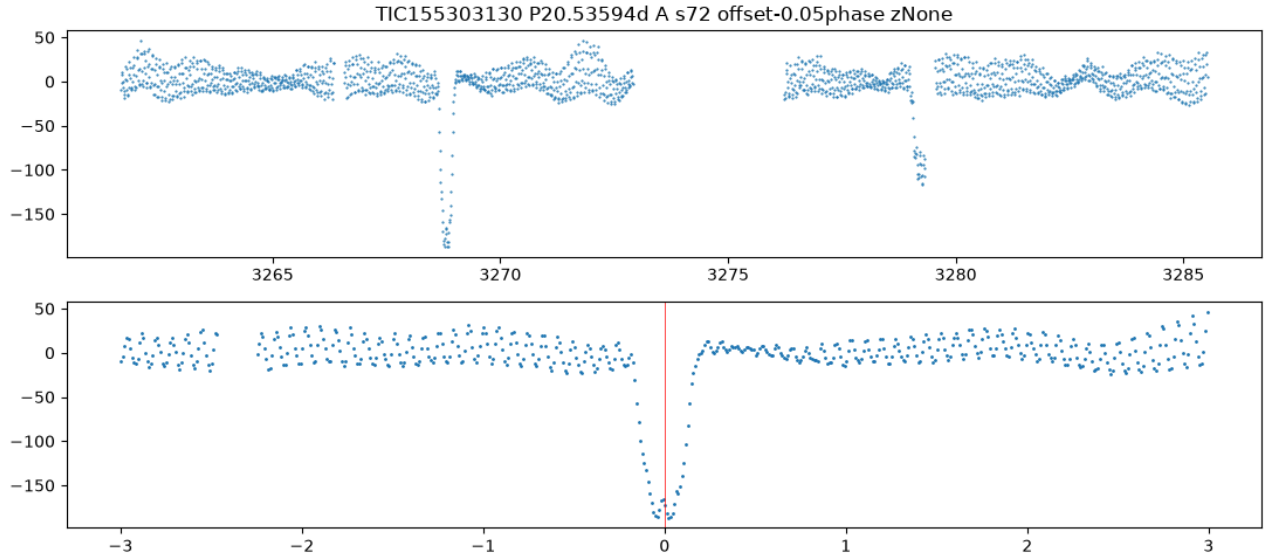
4. Alternative reduction: PASS as a processing check. Own TESScut extraction using median faint-pixel background and target 3x3 aperture reproduces deficit 98.38 ppt. The difference-stack receipt records per-event aperture depths. These are the same TESS photons, not an independent observing occasion; dilution/apertures explain differing QLP depths.
5. Gaia geometry: PASS for consistency, not a precision solution. Eclipse P differs from Gaia by -0.523 quoted Gaia period errors. B-conjunction epoch difference -0.522 propagated marginal-error sigma. Gaia mass function 0.0783 solar masses, minimum companion mass 0.736 solar masses for TIC primary mass 1.520. TIC R1=2.196 solar radii. Illustrative edge-on R2=1solar-radius duration at this conjunction 13.37 h, longer than observed; impact/inclination can shorten it. This is an existence/consistency check, not a fitted mass-radius claim. Correlated Gaia errors were not modeled; no arbitrary sigma veto.

Seven catalogue groups: fresh VSX60arcsec, ASAS-SN60arcsec, SIMBAD exactGaiaDR3, Gaia vari_eclipsing_binary exactID, Prsa2022 5arcsec, IJspeert2024 5arcsec, vetted Kostov2025 tables3+4 5arcsec all returned successful receipts. IJspeert contains exactTIC/Gaia. VSX DSCT and ASAS-SN ROT: classify the same star differently; its eclipses were already published. Full rows, UTC queries and response hashes are in catalogue coverage. The latter two Kostov tables form one group. No external messaging or public/paper edits.

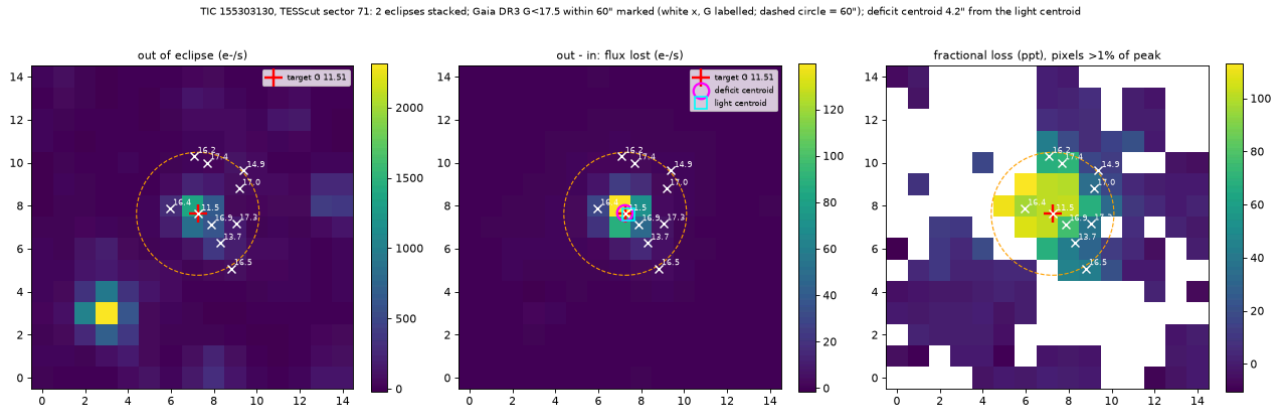
Limitations: Pilot characterization; period errors are scatter-only. No exhaustive literature priority claim. Next check: Supervisor review before admission; independent helper audit completed.

Lead audit: scripts inspected and deciding numeric outputs reconciled with raw SAP plots, full Gaia NSS metadata, source IDs and real TESScut pixels. Apparent failure/non-detection is not called physical refutation unless contrary evidence is present. Independent helper audit uncertainty caveats are retained. The helper verified deciding artifacts, not an exhaustive literature search.

Accepted review key: P024. Pilot selection and limitations, independent audit, and catalogue receipts. Nearby files contain the deciding pixel measurements and hashes. This public archive omits raw FITS and sanitizes local paths; scripts are archival rather than turnkey.



P024; fresh-155303130.png. Exploratory selection and photometric evidence; selection and period qualifications remain as stated.



P024; diff_pilot.png. Target-pixel deficit evidence; the near-orbital-period cases remain probable because capable close neighbours are unresolved.

period_error_days: 4.419206553916731e-05

period_error_meaning: OLSscatter standarderror; excludes cadence/template/systematic uncertainties

reference_epoch_btjd: 3979.672005735797

epoch_btjd: 3979.672005735797

epoch_kind: A

depth_ppt: 87.77880028840502

novelty_status: no prior EB identified in seven scoped groups; cachedChopardv1.2.0 exact IDs no overlap; laterreleases/embargo93 unknown

limitations: Pilot characterization; period errors are scatter-only. No exhaustive literature priority claim.

next_check: Optional precision characterization; no missing bounded admission check

Archived source: sanitized report text.

> Supervisor-accepted physical review: CONFIRMED. Included under the paper's stated physical tier and bounded catalogue scope. Earlier pending-admission wording below records the original handoff.

TIC 382042754: CONFIRMED

Scientific method/population: fresh Gaia-conjunction appointments G11.5-12 P20-60d. Physical review completion: complete bounded first pass, independently audited in helper/AUDIT.md; supervisor admission pending. Catalogue novelty is separate: no prior EB identified in seven scoped groups; cachedChopardv1.2.0 exact IDs no overlap; laterreleases/embargo93 unknown.

1. Repeated raw eclipses: PASS. 4 fit-eligible raw SAP events in sectors [96, 97, 98]. Trapezoid depths median 87.78 ppt; duration median 5.68 h. All saved events, rejected fits and raw files are identified in timing-results.json; no claim that other sectors are clean nulls. QUALITY==0 used. Existing raw observations were remeasured, not merely called eclipses from BLS.
2. Eclipse timing: PASS. P=25.8926723860 d; A-eclipse reference epoch BTJD 3979.67200574; OLS scatter SE 4.41920655e-05 d; residual RMS 0.133 min. This SE excludes cadence/template/extraction systematics and is not calibrated coverage. Fits are representative, not all-event precision ephemerides.
3. Target pixels: PASS. Sector 97, 2 event stack, peak pixel [7, 8] equals target [7, 8]; centroid-target 1.23 arcsec. 0 distinct Gaia neighbours could supply the flux under the conservative total-flux bound. All distinct Gaia neighbours within 60arcsec are too faint under the conservative bound. Catalogue incompleteness/unresolved companions are not excluded. Gaia position used consistently with

target ID. The older diffstack n_possible field includes the target itself; this report explicitly removes it.

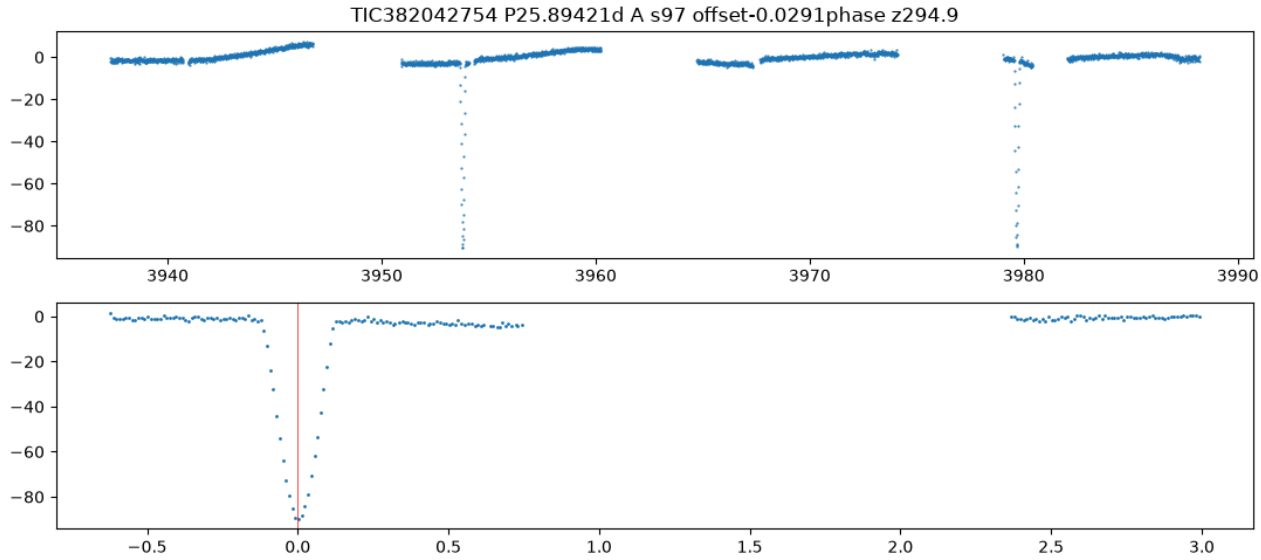
4. Alternative reduction: PASS as a processing check. Own TESScut extraction using median faint-pixel background and target 3x3 aperture reproduces deficit 90.79 ppt. The difference-stack receipt records per-event aperture depths. These are the same TESS photons, not an independent observing occasion; dilution/apertures explain differing QLP depths.
5. Gaia geometry: PASS for consistency, not a precision solution. Eclipse P differs from Gaia by -0.293 quoted Gaia period errors. A-conjunction epoch difference -0.911 propagated marginal-error sigma. Gaia mass function 0.1377 solar masses, minimum companion mass 0.835 solar masses for TIC primary mass 1.220. TIC R1=1.546 solar radii. Illustrative edge-on R2=1solar-radius duration at this conjunction 9.08 h, longer than observed; impact/inclination can shorten it. This is an existence/consistency check, not a fitted mass-radius claim. Correlated Gaia errors were not modeled; no arbitrary sigma veto.

Seven catalogue groups: fresh VSX60arcsec, ASAS-SN60arcsec, SIMBAD exactGaiaDR3, Gaia vari_eclipsing_binary exactID, Prsa2022 5arcsec, IJspeert2024 5arcsec, vetted Kostov2025 tables3+4 5arcsec all returned successful receipts. No on-target EB match in this bounded scope. Any VSX/ASAS-SN neighbour is retained as attribution evidence, not mistaken for target identity. Full rows, UTC queries and response hashes are in catalogue coverage. The latter two Kostov tables form one group. No external messaging or public/paper edits.

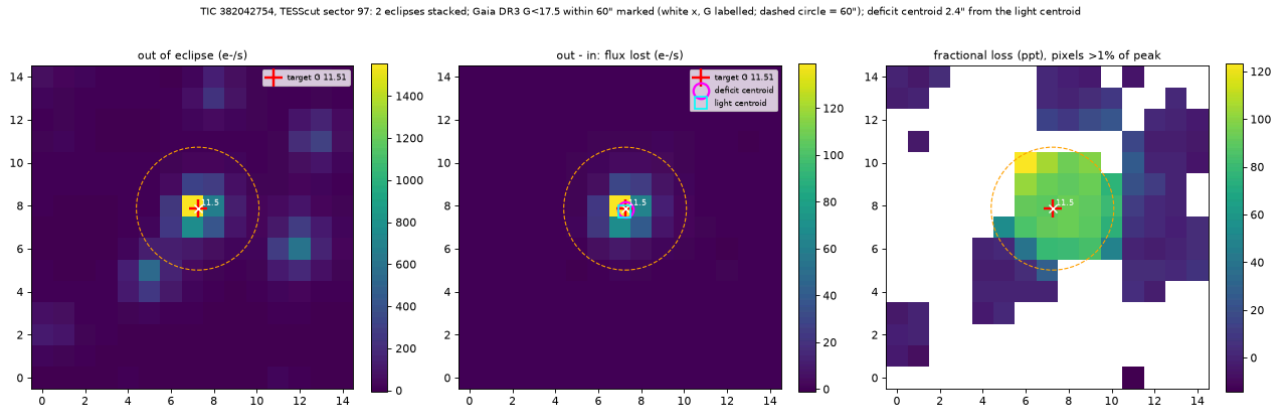
Limitations: Pilot characterization; period errors are scatter-only. No exhaustive literature priority claim. Next check: Supervisor review before admission; independent helper audit completed.

Lead audit: scripts inspected and deciding numeric outputs reconciled with raw SAP plots, full Gaia NSS metadata, source IDs and real TESScut pixels. Apparent failure/non-detection is not called physical refutation unless contrary evidence is present. Independent helper audit uncertainty caveats are retained. The helper verified deciding artifacts, not an exhaustive literature search.

Accepted review key: P025. Pilot selection and limitations, independent audit, and catalogue receipts. Nearby files contain the deciding pixel measurements and hashes. This public archive omits raw FITS and sanitizes local paths; scripts are archival rather than turnkey.



P025; fresh-382042754.png. Exploratory selection and photometric evidence; selection and period qualifications remain as stated.



P025; diff_pilot.png. Target-pixel deficit evidence; the near-orbital-period cases remain probable because capable close neighbours are unresolved.

P026. TIC 389128842 - CONFIRMED
